ACUTE AND CHRONIC BACILLARY DYSENTERY AND CHRONIC ULCERATIVE COLITIS

194
3

Joseph Felsen, M.D.
and
William Wolarsky, M.D., New York

During the past two decades there has occurred an increasing interest in the subject of the infectious diarrheas, particularly bacillary dysentery and chronic ulcerative colitis. It is our purpose to present the newer and poorly understood features of acute bacillary dysentery and to establish a relationship between it and chronic ulcerative colitis.

RISING INCIDENCE OF ACUTE BACILLARY DYSENTERY

In 1933, we directed attention to the inadequacy of available data on the prevalence of acute bacillary dysentery in the United States.[1] In 15 states it was not even a reportable disease. This condition was subsequently corrected through the cooperation of public health officials. We also pointed out new and atypical clinical forms of the disease and described a characteristic three stage progression of intestinal pathological change readily demonstrable at sigmoidoscopy. Due largely to the work of Boyd,[2] a more accurate classification of dysentery strains by serologic methods became available. There followed a rapidly rising incidence of reported acute bacillary dysentery that was assumed by many to be due largely to better recognition and reporting of the disease. Two decades have passed, and we must now revert to our original contention that there is an actual rising incidence of the disease. This is shown clearly in the accompanying graph (page 1070). It will be noted that, after reaching a peak of 38,313 cases in 1944, there was a gradual recession to approximately 17,000 cases in 1947 that was followed by a sharp secondary rise to 32,425 cases in 1951, the last year of available public health figures. It must also be remembered that the reported incidence of acute bacillary dysentery is but a fraction of the actual incidence because of failure to recognize the disease, inadequate study, and poor reporting. We wish to again call attention to the parallel rise in the unclassified dysenteries. The increase can no longer be attributed to better clinical recognition and reporting because these have been more or less stabilized for the past decade. Moreover, there appears to be no relationship to returning Korean War veterans. Our purpose in stressing the rising incidence of acute bacillary dysentery is to correlate it with other data indicating a probable relationship to chronic ulcerative colitis. The latter also appears to be on the increase, but precise information as to its numerical prevalence and to the existence of chronic ulcerative colitis in endemic or epidemic dysenteric areas is not available. It will remain so until our improvement in the diagnosis of chronic ulcerative colitis parallels that of other well-defined disease entities. Sole dependence on roentgenographic findings will lead to failure since defects of mucosal pattern, luminal stenosis, and rigid "stove pipe" colons are relatively late manifestations. Sigmoidoscopic findings, on the other hand, are manifested early in the disease. Edema and hyperemia of the mucosa, superficial erosions, and, above all, a purulent cellular structure of the aspirated mucosal exudate are early signs of chronic ulcerative colitis in a patient with long-standing bloody diarrhea.

PITFALLS IN CLINICAL DIAGNOSIS

The typical case of acute bacillary dysentery is readily diagnosed by the observant family physician and confirmed by culture of the intestinal discharges. Bloody diarrhea, abdominal cramps, and fever are unmistakable. But for every patient with these classic symptoms and signs, there are many more without them. This is certainly true of the disease as it has been encountered in the United States since 1932. During our studies of the Jersey City epidemic at the Medical Center in 1934,[3] sigmoidoscopic examination revealed the characteristic three stage progression of intestinal lesions, namely diffuse hyperemia of the mucosa with punctate follicular hyperplasia, punctate follicular necrosis, and discrete or confluent ulceration on the first, second, and third days, respectively, of the disease. Infants might die during stage

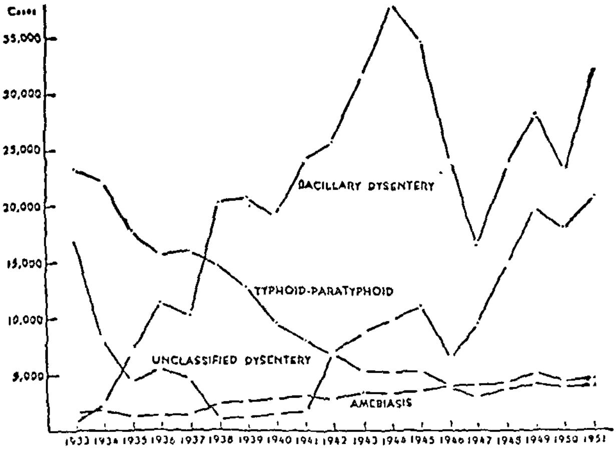
1 or 2, while some adults had few or no symptoms even in stage 3. This was determined by examining all contacts regardless of the presence or absence of symptoms. *Cultures proved positive for Shigella dysenteriae, and* there was a rising serologic titer, positive phage, and purulent cellular structure of the mucosal exudate. Seven atypical clinical forms were classified as the afebrile, asymptomatic, constipated, meningitic, pneumonic, appendicular, and agranulocytoid. The potential hazards *offered by these previously unrecognized cases were* apparent. They were sometimes more responsible for spread of the disease than patients who were acutely ill and confined to bed. The lesson to be learned from these observations was that, in dealing with acute bacillary dysentery, every contact must be cultured if the disease is to be effectively controlled. Periodic mass surveys in endemic or epidemic areas would be a progressive public health measure. It was also evident that, clinically, acute bacillary dysentery should be regarded as a systemic disease with focal intestinal manifestations, since the extraenteric symptoms and signs often overshadowed the *diarrhea, especially at the onset and most infective stage* of the disease.



Incidence of bacillary dysentery, typhoid and paratyphoid, unclassified dysentery, and amebiasis from 1933 to 1951. Note concomitant rise in unclassified and bacillary dysentery in 1949.

The sigmoidoscopic picture as described above is diagnostic of acute bacillary dysentery. The failure to institute such an examination is generally due to fear of perforating the bowel, lack of familiarity with *interpretation of the pathological changes of the intestine, or* unwillingness on the part of the patient. These are not serious drawbacks, and they can readily be overcome by appropriate educational measures. We teach our residents to handle the sigmoidoscope as an artist does his *brush, to remove the obturator as soon as the instrument* is in the ampulla, then to proceed by direct vision, and, if he must use force, to do so only in removing the scope—a purely facetious statement for psychological effect. The danger of perforating the bowel is negligible in the hands of an experienced examiner. *If a one-half inch (1.27 cm.) sigmoidoscope, a ×10 magnifying telescope,* and a heavy-walled capillary pipette for aspiration of the mucosal exudate are used, the entire procedure lasts only a few minutes. The mucosa and lymph nodes are examined for the characteristic changes. A few drops *of the mucosal exudate are then aspirated,* and part is used for culture by *spraying on a quadrant culture dish* containing four differential mediums.[4] The *other part is* examined on a slide in order to determine the characteristic purulent cellular structure.

INADEQUACY OF BACTERIOLOGICAL STUDIES

Bacteriological studies are usually inadequate because of procrastination on the part of the physician or patient. When a local laboratory is not readily available, the state public health laboratory is no further than the mailbox. The feces *may be mixed with formaldehyde to a concentration of 1:10,000, or with 30% glycerin. Specimens* may be shipped air mail. Such studies are important not only because they protect the community but also because they furnish accurate data for clarifying our under*standing of the chronic forms of the disease. It may be in one of these very patients in whom chronic ulcerative* colitis or ileitis subsequently develops within a year. Cultures for Sh. dysenteriae usually become negative after 7 to 10 days in the average case of acute bacillary dysentery so that, if the chronic phase has developed, *bacteriological search for specific primary enteric pathogens* is futile in most instances. This explains the absence of positive cultures for Sh. dysenteriae in the majority of cases of chronic ulcerative colitis. Convalescent carriers are sometimes encountered, but the carrier state usually *does not last more than a month, very rarely for a year.* It is more important to establish the initial diagnosis and culture with adequate follow-up than to rely solely on recovery of the dysentery organism a year later when chronic ulcerative colitis is present.

INTESTINAL LESIONS

The stereotyped textbook picture of the intestinal lesions presented to medical students three decades ago is rarely seen in the United States. For *every patient in whom the colon is almost completely* denuded of mucosa with massive hemorrhage, there are perhaps 20 in whom the lesser lesions described above are found. This change in the concept of the pathological changes in acute bacillary dysentery may possibly *be due to lessened* susceptibility of the host or lowered virulence of the organism. We suspect, however, that the three stage progression of disease process also occurred prior to 1933 but that it was never observed due to the omission *of sigmoidoscopic examinations in the living* patient or perfunctory study of the bowel at necropsy. We teach our residents to examine opened intestines at necropsy carefully by reflected and transmitted light from a light box. This simple method has yielded a wealth of interesting data previously overlooked.

IMPORTANCE OF FOLLOW-UP STUDIES

Every patient with infectious diarrhea should be reexamined by sigmoidoscope at three month intervals for one year. Fortunately, *in most cases intestinal lesions are easily discernible in the distal colon.* Rare skip or proximal lesions can usually be detected by roentgenography. The chronic or persistent intestinal changes may be present even in patients who have few complaints, such as occasional diarrheal movements specked with blood often erroneously attributed to hemorrhoids. Intestinal bleeding (bright red blood) is an important sign in many serious conditions of the digestive tract, and even in the presence of hemorrhoids no conclusions should be drawn without visual inspection of the bowel above.

ANTIBIOTICS VERSUS SULFONAMIDES

Neither antibiotics nor sulfonamides are of prophylactic value in bacillary dysentery, and they should not be used for this purpose since they tend to favor the development of mutants or resistant strains and adversely influence vitamin synthesis if used over a long period of time. For curative therapy, a combination of sulfathiazole or sulfadiazine and succinylsulfathiazole (Sulfasuxidine) or phthalysulfathiazole (Sulfathalidine) is effective. The table shows the range of usefulness of the antibiotics. Oxytetracycline (Terramycin), chloramphenicol (Chloromycetin), and possibly chlortetracycline (aureomycin) appear to be most effective for the strains usually encountered. If uncertainty exists, in vitro sensitivity tests should be carried out against the particular dysentery organism involved. Recent studies in Korea indicate the failure of sulfadiazine in Flexner infections, chiefly 3 and 4.[5] The antibiotics have proved effective in sulfonamide-resistant cases of acute bacillary dysentery, but we are also beginning to encounter antibiotic-resistant strains of B. dysenteriae. This merely reflects a normal biological response on the part of the dysentery organism. The same phenomenon has occurred in staphylococcal infections due to the indiscriminate and prolonged use of penicillin.[6] Allergic manifestations may occur after the use of either sulfonamides or antibiotics, and renal complications may follow the use of the absorbable sulfonamides. Chloramphenicol is still a vauable antibiotic in intestinal infections caused by gram-negative organisms in spite of rare instances of granulocytopenia or agranulocytosis produced by it.

CHRONIC BACILLARY DYSENTERY

Patients who do not recover from an attack of acute bacillary dysentery usually exhibit intestinal lesions that are considered characteristic of chronic ulcerative colitis. Adequate interval observations have revealed that these merely represent a perpetuation of the lesions produced during the acute specific phase with a superimposed nonspecific infection. This subject is still controversial, although there appears to be a general agreement that some, but not all, cases are due to bacillary dysentery. Many other theories as to etiology[7] have been offered; this is due at least in part to the fact that positive cultures or a definite history of acute bacillary dysentery are obtained only in a limited number of cases of chronic ulcerative colitis. The relative paucity of carrier states in bacillary dysentery and the many cases undiagnosed because of the occurrence of atypical clinical forms should adequately explain the failures to associate chronic ulcerative colitis with a previous attack of acute bacillary dysentery. Under carefully controlled conditions, such as in the Jersey City epidemic of 1934,[8] there was not the slighest doubt of the antecedent history or diagnosis. Of an original group of 210 patients hospitalized at the Medical Center, follow-up studies of 122 showed that in 10.7% chronic ulcerative colitis or distal ileitis developed at the end of 9 to 12 months. These findings have been corroborated elsewhere by other investigators.[9] The amazing fact is that, in the light of such impressive data, we have failed to adequately control acute bacillary dysentery. Such action would be fully warranted even if only a small proportion of the cases of chronic ulcerative colitis were due to bacillary dysentery. It would seem wise to institute a rigid campaign to control bacillary dysentery in the same manner as typhoid and to note the effect of such control on the incidence of chronic ulcerative colitis or ileitis. This should give rise to serious reflection. Pathologically, the intestinal lesion in acute bacillary dysentery and chronic ulcerative colitis involve identical areas—all or part of the small or large intestine. In both there is a predilection for the distal ileum and the proximal and distal colon. The ileocecal valve is no bar to extension of the infection, and our original contention that ileal involvement occurs in chronic ulcerative colitis has been confirmed. The presence of granulomatous giant cells in ileitis does not nullify the common identity of the histopathological changes in both diseases.

Sensitivity of Shigellae to Antibiotics in Vitro*

Antibiotic	Sensitivity of Strains
Penicillin	None
Chlortetracycline (aureomycin)	Moderate
Chloramphenicol (Chloromycetin)	High
Oxytetracycline (Terramycin)	High
Streptomycin	Relatively low
Dihydrostreptomycin	Relatively low
Bacitracin	None

* 12 strains tested by disk method: Shigella dysenteriae, ambigua, 8 types of flexneri, sonnei, and aklalescens.

In a recent review of 1,072 of our cases of chronic ulcerative colitis and ileitis (chronic ulcerative colitis, 994 cases; ileitis, 31 cases; and combined form, 47 cases), positive cultures for Sh. dysenteriae were found in 75 (7%) as compared with 0.08% in 6,000 controls, including monthly repeat cultures on the same persons for many years (food handlers and nursing personnel) at the Bronx Hospital. A definite epidemiological history (knowledge of the disease having started during an outbreak in an endemic or epidemic dysenteric area) was obtained in 236 and multiple familial contact infections occurred in 24.

Beside the question of etiology, there are other problems of recent interest in chronic ulcerative colitis that will be discussed briefly. These concern pregnancy, carcinoma, and the use of newer therapeutic agents.

PREGNANCY

Pregnancy generally has a salutory effect on chronic ulcerative colitis.[10] Rarely is termination of pregnancy indicated. Our own experience covers 117 pregnancies in 72 patients. During 59 of these pregnancies, the patients felt well symptomatically, and this state was reflected by improved or absent sigmoidoscopic findings. In 39 pregnancies, although the patient was not well, the disease had no significant effects on the pregnancy. In five patients, the disease started during pregnancy; these are included in the group of 39. The disease in these five was no worse than in the other 67 patients in whom it antedated the pregnancy. In eight pregnancies, colitis was quiescent during pregnancy but was definitely worse after delivery. In 11 instances, the data were incomplete, and no conclusions referable to the pregnancy or ulcerative colitis could be drawn. Prematurity occurred in one instance and was complicated by retrolental fibroplasia.

CARCINOMA

Carcinoma[11] occurred in 7 (0.65%) of 1,072 of our patients with chronic ulcerative colitis, but there was no evidence that there was any relationship between the two diseases. Our data include patients of varying ages and follow-up periods. Control studies of similar groups in 12,025 general admissions without ulcerative colitis at the Bronx Hospital during 1946 and 1947 revealed an incidence of intestinal carcinoma of 0.8%. Pseudopolyposis in our opinion is but one stage in the inflammatory process in chronic ulcerative colitis. It consists of bits of pinched off mucosa from which regeneration of epithelium occurs to cover denuded areas. Pseudopolyposis frequently occurs at one stage or another in chronic ulcerative colitis and is not to be confused with adenomatous polyps that are neoplastic and exhibit a definite tendency to malignancy.

TREATMENT

The sulfonamides, antibiotics, cortisone, and corticotropin (ACTH) are palliative, not curative, therapeutic agents in chronic ulcerative colitis. Their prolonged use is to be deplored. In the case of the antibiotics and sulfonamides, they lead to the development of resistant strains and may mask dangerous complications.

Surgery is indicated in a small percentage of patients. Any decision must be individualized for each patient, and the surgical hazards, possible failures, and psychological effects must be kept in mind. Ileostomy does not cure ulcerative colitis or stop massive hemorrhage from the colon. While the mortality of this procedure alone has been reduced from about 25 to 4%, very troublesome complications, such as retraction of the stoma, prolapse, and perforation, do occur. The present tendency to do an ileostomy and total colectomy including removal of the rectosigmoid segment in one stage is radical but has a surprisingly low mortality in selected cases.

Friedlander, while at the Ft. Hamilton Veterans Administration Hospital, performed 23 primary resections with two postoperative fatalities (8%). Ripstein, at Maimonides Hospital, did 122 such procedures with five postoperative deaths (4.1%). Dennis, at New York State University, carried out 53 primary resections with one postoperative death (1.9%). Cave prefers the two stage procedure with eventual removal of the distal segment. It is of interest that, in a series of 156 resections, Cave encountered 14 instances (9%) of carcinoma developing in the distal segment. Garlock carries out primary resections only in selected cases in the ordinary chronic form of the disease but not at all in acute cases with massive hemorrhage. Patients with the latter stand the one stage procedure poorly. The procedure takes 4 to 5 hours in experienced hands and must be accompanied by flawless preoperative, operative, and postoperative care, particularly with regard to fluid and electrolyte balance. Operative mortality figures depend largely on the severity of the disease and suitability of the patient for radical surgery.

Most surgeons prefer the two or three stage procedure with removal of the distal segment in all cases. It is generally conceded by surgeons that chronic ulcerative colitis is primarily a medical problem. Surgery should not be withheld, however, until the condition becomes desperate and the risk correspondingly greater. This is largely a matter of clinical judgment, since some patients make dramatic recoveries after massive hemorrhage without surgery and others die of fulminating chronic ulcerative colitis months after an ileostomy. Surgery should be considered in patients intractable to medical therapy and for complications such as uncontrollable hemorrhage, fistulous tracts, and intestinal obstruction. Perforation is attended by an extremely high surgical mortality and is best treated conservatively. Arthritis, erythema nodosum, and necrotizing skin lesions are not indications for surgery and yield to adequate medical therapy. In our experience, all three have a good prognosis. Periarthritic manifestations occurred in 187 (17.4%), erythema nodosum in 15 (1.4%), and necrotizing skin lesions in 16 (1.5%) of our 1,072 cases.

SUMMARY AND CONCLUSIONS

The rapidly increasing incidence of acute bacillary dysentery in the United States is discussed, and evidence is presented that indicates a relationship between acute bacillary dysentery, chronic ulcerative colitis, and ileitis. The more recent studies in the epidemiology, bacteriology, pathology, and clinical aspects of these diseases indicate the strong probability that the ideal therapy of ulcerative colitis and ileitis is the prevention of acute bacillary dysentery.

ENDOTRACHEAL ANESTHESIA FOR TONSILLECTOMY AND ADENOIDECTOMY IN CHILDREN

John W. Pender, M.D.
and
O. Erik Hallberg, M.D., Rochester, Minn.

The use of endotracheal methods of anesthesia has been widely accepted for adults. For children, such methods are standard in many operations, especially those about the head and neck, such as craniotomy and cleft palate. The use of endotracheal anesthesia for tonsillectomy and adenoidectomy in children has gained favor slowly in spite of its being the routine method of general anesthesia for tonsillectomy in adults in many hospitals. We believe that the advantages of endotracheal anesthesia for tonsillectomy and adenoidectomy are as great for children as for adults, if not greater, and in our experience the disadvantages have been encountered no more frequently and they have been of no greater magnitude in children than in adults.

ADVANTAGES

The endotracheal tube serves as an airway that is continuously patent in contrast to the frequent obstruction to respiration that occurs during tonsillectomy when an endotracheal tube is not used. A continuously patent airway makes it possible to avoid the development of cyanosis and hypoxia in all patients. Since inhalation anesthesia can be carried on continuously without danger of interruption, a lighter nonvarying level of anesthesia can be maintained throughout operation and the protective laryngeal reflexes become active rapidly after operation. When the endotracheal tube fills the larynx, the passage of blood and other foreign material from the pharynx into the trachea and bronchi is minimized. The dangers of postoperative abscess of the lung and other pulmonary complications are thereby decreased. Steele and Anderson[1] reported aspiration of blood from the trachea in 96.9% of 129 patients who underwent bronchoscopy after tonsillectomy under general anesthesia without endotracheal tubes. In our patients in whom endotracheal tubes were used, bloody secretion could rarely be aspirated from the trachea since the endotracheal tube was removed at the end of the operation. The tube serves, however, as an easily accessible approach through which excessive tracheal and bronchial secretions may be aspirated. This makes postoperative bronchoscopy rarely necessary.

The greatest advantage of endotracheal anesthesia for tonsillectomy and adenoidectomy is the freedom with which the tongue may be retracted to allow excellent surgical exposure without danger of occlusion of the airway. In all our cases, the tube was passed through the mouth, but, instead of visualization of the field of operation being impaired by the tube, it was improved. It may sound paradoxical to the surgeon who has not tried it, but there is more room for operating when the tube is in the mouth than when it is not used, because freedom of retraction of the tongue is allowed by the presence of the tube. When the surgeon is removing the left tonsil, the tube is held in the right corner of the mouth and descends along the right border of the tongue well away from the site of operation. When the surgeon is ready to remove the right tonsil, the anesthetist can move the end of the endotracheal tube to the left corner of the mouth and the pharyngeal aspirator can be used to move the tube to the left border of the tongue. For adenoidectomy, the tube can be put in whichever side of the mouth suits the surgeon's technique best.

DISADVANTAGES

With the rules and techniques we have followed, the disadvantages of endotracheal anesthesia have been minimal. From 1946 to 1951 inclusive, 1,050 endotracheal intubations were performed at the Mayo Clinic for tonsillectomy or adenoidectomy, or both, in patients less than 15 years of age. The only complication or inconvenience that could be attributed to the intubations was displacement of the endotracheal tube from the larynx; this occurred twice during operation. It is likely that some minor complications of intubation, such as transient sore throat, were not detected because of the nature of the operation, but no major complications, such as laryngeal edema necessitating tracheotomy, occurred. The one possible disadvantage of this type of anesthesia is that the services of a trained anesthetist are required.

GENERAL RULES

Not having experienced any serious complications, we cannot say with certainty what procedures and techniques of intubation should not be used. The following general rules are those that were successfully followed to avoid complications of intubation in our young patients.

Avoid Trauma During Intubation.—Various methods of inducing anesthesia were used, but before intubation all patients received ethyl ether to produce moderate surgical anesthesia so that pharyngeal and laryngeal reflexes were abolished. The vocal cords were gently exposed by holding the laryngoscope lightly between the fingers and avoiding the use of force. Contrary to the opinions of some authors, intubation was found in general to be less difficult in children than in adults. Our insistence on moderately deep anesthesia with a potent agent may account for the difference between our experience and that of others. Once the tube is in place, very light anesthesia was all that was needed, that is, just enough to keep the patient from swallowing or coughing. Frequently after intubation the administration of ether could be discontinued and the

operation completed with the administration of nitrous oxide and an adequate concentration of oxygen. Several methods were used for delivering the anesthetic gases and vapors from the anesthesia machine—circle absorption, nonrebreathing valves of the Leigh type, Ayre's "T" arrangement, and the Flagg ether can. All methods served satisfactorily for the short duration of anesthesia necessary for tonsillectomy and adenoidectomy.

Select Endotracheal Tube of Correct Size.—A tube was selected to fit each patient rather than to conform with age or weight. Before intubation, several sizes and lengths of tube were prepared and made available on a tray. After the vocal cords were exposed, a tube was selected that would fill the larynx loosely. If the slightest resistance was encountered in passing a tube between the cords, that tube was discarded and the next smaller size used. Tables 1 and 2 show the sizes of endotracheal tubes used for the various age and weight groups. It will be seen that in each group a rather wide range of tube sizes was necessary to effect the proper fit of tube to larynx. The distance from the upper incisor teeth to the level of the second costal cartilage was a rough indication of the length of tube needed; however, just as the tip of the tube passed the vocal cords the anesthetist focused his vision on the length of the tube remaining outside the mouth and was able to judge how much farther to advance the tube so that the tip would lie in the middle third of the trachea.

Avoid Motion of Tube in Larynx.—The head of the patient was held firmly in position by the anesthetist. The tube was moved gently and as infrequently as possible. The short duration of tonsillectomy and the natural position of the head during operation make postintubation complications less likely to occur after tonsillectomy than after longer operations, such as craniotomy, during which much movement of the patient's head is likely to occur. Table 3 shows that the duration of intubation was short in most of our procedures. As soon as the tonsillectomy was completed, the patient was turned to the prone position with the tube in place to allow pharyngeal secretions and blood to drain out by gravity. The tube was removed as soon as the patient began to swallow; this usually occurred within a few minutes after the nitrous oxide anesthesia was stopped. Swallowing and coughing when the tube is in place may cause trauma to the larynx.

Use Only Chemically and Bacteriologically Clean Tubes.—No attempt was made to maintain strict asepsis of endotracheal tubes, but contamination was prevented. After use, the tubes were washed inside and out with soap and water on a brush. They were then boiled 5 minutes or soaked for 30 minutes in an antiseptic solution, such as 1:1,000 solution of benzalkonium (Zephiran) chloride, which does not penetrate the rubber. After being thoroughly rinsed and dried, the tubes were stored in curved plastic containers or sterile towels. Application of a lubricant to the tube before use is not necessary, but, if one is used, it should be sterile and nonirritating and should be applied with a sterile sponge. Care was exercised to prevent the part of the tube that was to pass through the vocal cords from being contaminated by fingers or other unsterile objects before the tube was passed into the trachea.

CONCLUSIONS

The advantages of endotracheal anesthesia for tonsillectomy and adenoidectomy are as great for children as for adults, if not greater. Our experience indicates that the disadvantages of properly executed endotracheal anesthesia for tonsillectomy and adenoidectomy in children have been overemphasized. The endotracheal tube does not in any way obstruct the working space of the surgeon; in fact, visualization is improved.

CORONARY DILATORS AND ANGINA

REAPPRAISAL

Earl N. Silber, M.D.
and
Louis N. Katz, M.D., Chicago

The physiology of the coronary circulation and the problems of human coronary disease have been under investigation for over 20 years in this department. It is our purpose to reexamine certain aspects that form the basis for the clinical use of coronary vasodilator drugs and to summarize our results with several of the preparations in current use.

Drugs that dilate the coronary vessels are useful. The usefulness of a drug, however, does not lie simply in the demonstration of such dilatation. Of equal importance is the necessity of ascertaining that such drugs do not divert blood from the coronary circuit by a disproportionate dilator action on one or more of the other systemic circuits. Under such circumstances, even a coronary dilator drug may leave the coronary flow unchanged or actually decreased. Secondly, it must always be established that drugs that increase coronary flow do not at the same time increase the metabolism or work of the heart proportionately or disproportionately and thereby nullify the anticipated benefits. Epinephrine (Adrenalin) is one drug that has this dual effect.

The term coronary insufficiency, as an expression of inadequate nourishment of the heart by its circulation, has served a useful purpose. It has created a concept of coronary disease that incorporates physiological factors as well as purely anatomic changes in the vessels. The concept that coronary insufficiency is measured by angina pectoris is fallacious. Such a view takes no cognizance of the fact that angina pectoris is pain and, in this sense, must be analyzed in terms of the physiology of sensation —quite apart from factors having to do with coronary flow.[1] This involves an appreciation of the location and variable level of threshold of pain endings in the heart, the mechanism of referred pain, and the psychology of pain appreciation. To the clinician without such knowledge, the occurrence of angina, unrelated to effort, remains an unexplainable mystery.

Our knowledge of the effect of drugs on the coronary circulation is derived from animal experiments employing various types of isolated hearts, the heart-lung preparation, or the heart beating in situ. In the first two methods, conditions were usually carefully controlled by denervation, cannulation, elimination of contraction, and use of a constant perfusion pressure. In such preparations, changes in flow can result only from alteration in the caliber of the coronary vessels. We have, at one time or another, used each of these preparations. Most of the drugs examined, with the exception of vasopressin (Pitressin), foreign species blood, and potassium in high doses, were found to be coronary vasodilators. Such experiments give little indication of the effect of these drugs on the heart itself or any information of extracardiac effects, such as on blood pressure, pulse rate, and respiration, that may nullify the coronary effect. It should also be borne in mind that drugs that are potent when introduced directly into the circulation of experimental preparations may be completely inert or may possess only a weak or evanescent effect when administered orally.

CLINICAL EVALUATION

Animal experiments show what happens under a specific set of circumstances and serve as a first line of investigation. The effect of these drugs must then be investigated in patients with coronary disease. This brings us to the problem of the clinical evaluation of coronary dilator drugs. It is apparent, from even a casual survey of the literature dealing with the medical treatment of angina, that confusion and conflicting reports surround the use of each of the coronary drugs currently in favor. Such discrepancy in results has as its basis the poorly designed clinical experiment. In this regard, several factors are of major importance; some concern the object of the study, others the investigator.

One must first appreciate the marked variability in the incidence and severity of pain that occurs in patients with angina who are receiving no therapy whatever. These vagaries occur not only under the influence of season, climate, disease in other organ systems, and emotional disturbances but also under apparently unchanging conditions. All of us have at some time observed a decline in attacks of anginal pain with a concomitant rise in the stock market! Because of such variability, the conviction has grown in our department that observations of the effect of coronary dilators should be made for a minimum of one year in a large group of patients. "Small, but carefully observed" groups constitute a type of selection that, in itself, may lead to incorrect conclusions. Second, in choosing patients for study, only those with severe angina should comprise the group. By severe, we refer to patients experiencing a minimum of several attacks of angina a day. Statistically, it may be said of a patient experiencing 1.5 attacks per week before treatment and only 0.6 attack per week while under treatment that he has shown an improvement of "more than 50%." From a realistic standpoint, however, the difference is not significant, yet value is repeatedly attached, in the literature, to drugs on the basis of such meager evidence. On the other hand, one cannot categorically deny the value of a drug in angina when unequivocal benefit is seen in only a small percentage of cases. Furthermore, while severe angina is preferable for testing therapy, it is conceivable that the very severity of the angina may, on occasion, lead to negative results, whereas in milder forms a drug may actually have value.

[1] Katz, L. N.: Mechanism of Pain Production in Angina Pectoris, Am. Heart J. **10**: 322, 1935.

It should hardly be necessary to advise, in the study of so highly a subjective ailment as angina, the need for repeated substitution of a placebo for the therapeutic agent. Mention should be made, in this regard, of patients who respond readily to the "ceremony of therapy." These are persons who show improvement regardless of what drug is used. They get better, as far as angina is concerned, even when a placebo is used in the double blind test. The question arises whether their use in tests of drugs that might relieve angina does not decrease the accuracy of a study. It is our present conviction that such patients are not suitable for this type of clinical evaluation and perhaps should be separated in clinical surveys from those who are not so obviously susceptible to the ceremony accompanying therapy.

BIAS

Finally, bias on the part of the investigator, whether it is conscious or unconscious, is a major source of error in such clinical studies. In its more benign form, this expresses itself by an enthusiastic approach on the part of the observer or through suggestion by use of leading questions. Speaking editorially in a recent issue of THE JOURNAL, Beecher [2] pointed out that "Observation is difficult enough when objective signs are under consideration; it is more difficult when subjective responses are examined. Then not only is the patient's sending station of doubtful accuracy but the observers reception of the signals is confused by extraneous noises produced by tradition, by confusion derived from his own more or less acute perception, by his failure to seek patiently for the truth, but most of all by bias."

Our earlier clinical experience with papaverine [3] and visammin (khellin)[4] made us realize in 1949, that in any such study not only the patient but the observer must be unaware of whether active drug or placebo is being administered. This technique has been termed the double blindfold method by others.[5] We have relied solely upon relief of pain as a criterion of the efficacy of a particular agent. We have rejected exercise tolerance or hypoxemia tests because response to these procedures varies spontaneously in patients and requires repeated testing over long control periods to make their use at all worth while. More important, these tests are artificial and are not comparable to the clinical situation that evokes anginal pain. It cannot be shown that there is a high correlation between the ability of a drug to prevent electrocardiographic changes under stress and to prevent anginal pain.

In 1949, employing the double blindfold method, we investigated the effect of dioxyline phosphate (Paveril) on 20 patients with severe angina.[6] In these patients, observed up to six months, no benefit was noted. In our studies of pentaerythritol tetranitrate (Peritrate) in 1950, we found that it exerted no significant benefit.[7] Many of the patients on whom this drug was tested were previously subjects for the study with dioxyline phosphate, and the vagaries of their angina had been well characterized.

In 1950, in the resurvey of visammin, we made the drug available to members of the attending staff at Michael Reese Hospital for use in their private practice. It was understood that, as they reported their results to the dispensing agent of this department, substitution of drug for placebo or placebo for drug would be made without their knowledge. By this technique, it was not possible to demonstrate significant relief of pain in any but an occasional patient.[8] Side-reactions occurred in a third of such patients and necessitated discontinuance of the drug in 50% of the group. When confronted with the data of such blind testing, the staff soon could not be induced to continue the use of visammin.

We have had no reason to change our mind with respect to papaverine from the opinion expressed in the study of Simon and his associates in 1949.[9] Here, as elsewhere procaine amide (Pronestyl) hydrochloride or quinidine have practically supplanted the use of papaverine in abolishing ectopic ventricular rhythms.

At present, we are observing the effect of estrogens on the anginal syndrome. This is not a study of coronary dilators but of agents acting on coronary wall lesions. The ability of these substances to prevent [10] or induce [11] regression of coronary atherosclerosis looms as a highly promising lead. It is much too early to speak of results.

SUMMARY AND CONCLUSIONS

An attempt is made to point out what have continued to appear as important concepts in the treatment of coronary disease. The pitfalls of clinical observations in this area are emphasized. Rigid attention to such sources of error in clinical investigations on angina pectoris would go a long way in resolving the value of the multiple forms of therapy now currently employed and would give security in testing new ones.

Sunlight Flavor in Milk.—Exposure of milk to daylight, in conventional glass milk bottles, for periods of about ½ hour or more produces an objectionable flavor commonly known as "sunlight" or "activated." Wavelengths of light in the visible spectrum are responsible for the flavor. Incident to its production, most of the ascorbic acid and a substantial part of the riboflavin in the milk are destroyed. Therefore, sunlight flavor in milk has important economic and nutritional implications. Sulfur-containing compounds are associated with the flavor. . . . The importance of methionine in sunlight flavor production first was suspected when exposure of dilute aqueous solutions of this amino acid was observed to develop a flavor apparently identical with that produced on exposing milk. Further study revealed that the addition of methionine in quantities as little as 4 mg./qt. greatly enhanced production of the flavor in skim milk.—S. Patton and D. V. Josephson, Methionine—Origin of Sunlight Flavor in Milk, *Science,* Aug. 21, 1953.

EMERGENCIES IN THE NEWBORN

George Cooper Jr., M.D., McLemore Birdsong, M.D.
and
Randolph Bradshaw, M.D., Charlottesville, Va.

An editorial in THE JOURNAL, Feb. 7, 1953, stated, "Although there has been a remarkable decrease in rate of death in the first year of life during the past quarter of a century, the number of infants dying in the first 24 hours of life has diminished but little." The editorial was stimulated by Fischer's article "The First Day of Life, the Physician's Responsibility," which appeared in the November, 1952, issue of the *Medical Clinics of North America.* As Fischer emphasized, since 1945 an infant's chance of dying has been greater during the first day of life than at any time between the 2nd and 12th months (fig. 1). He commented, "That this cannot be lightly passed off (as) due to the absence of medical care at birth is . . . proved by the fact that in 1950 . . . in Philadelphia, where 95 per cent of infants are born in hospitals . . ., 534 of the 47,680 newborns failed to live beyond their first day." As can be seen in the graph, the decline in death rate during the first month of life, as well as the first day, has not kept pace with the decline in the period from the 2nd to 12th month.

The joint session of the pediatrics and radiology sections of the American Medical Association is a fitting occasion for a discussion of the more important indications for roentgenologic examination of the newborn. Prompt, accurate diagnosis and prompt, skillful treatment can alter the figures, in spite of the fact that prematurity and uncorrectable congenital deformities are the greatest obstacles to improvement.

RESPIRATORY AND CIRCULATORY EMBARRASSMENT

Of the indications for roentgen examination of the newborn, those suggesting abnormalities of the lungs and diaphragm are usually the earliest discovered. They may be conveniently discussed as a group and consist chiefly of cyanosis, respiratory irregularity, thoracic respiratory effort, gross inequality of respiratory excursion, percussion dulness, and physical signs of mediastinal shift.

While the assistance of roentgen diagnosis must be sought freely if correctable abnormalities are to be discovered and treated promptly and successfully, transient mild cyanosis, respiratory irregularity, and perhaps even intermittent thoracic respiratory effort can occur without serious significance, especially in premature babies. Since disturbance of these delicate infants is undesirable, even for so simple a procedure as a roentgenographic examination of the chest, good judgment must be displayed in the clinical evaluation of symptoms. Roentgen examination should be employed frequently but not routinely. On the other hand, when there is persistent thoracic respiratory effort, gross inequality of respiratory excursion, or percussion dulness or when physical signs of mediastinal shift are observed, roentgen examination of the chest is almost certain to yield valuable information and should be performed promptly. An emergency situation is often discovered.

Pulmonary Maldevelopment.—Roentgen examination contributes significantly to the recognition of pulmonary aplasia and hypoplasia. Conclusive diagnosis requires bronchography as well as conventional chest films. The chief importance of the recognition of these abnormalities is prognostic. They are compatible with a normal life span, though it may be necessary to give the baby an increased amount of oxygen until an initial respiratory embarrassment is overcome.

Atelectasis.—Recognition of incomplete expansion of the lungs is chiefly of prognostic value. As demonstrated in 1933 by Wilson and Farber,[1] a varying amount of nonaeration is physiological in the first few days in normal, full-term babies and in the first four to six weeks in premature infants. But atelectasis secondary to obstruction of a bronchial lumen is absolutely not physiological. Differentiation between the two is vital and requires close cooperation between pediatrician and roentgenologist. Incomplete expansion requires no treatment, but the relief of obstructive atelectasis by bronchoscopy and suction is an emergency procedure that reduces morbidity and mortality.

Pulmonary Hyaline Membrane Syndrome.—In the case of pulmonary hyaline membrane, recognition depends on close cooperation between pediatrician and roentgenologist. There are many unsettled controversies as to its pathogenesis and chemical nature,[2] but Meschan and his associates [3] have pointed out recently that the initial phase of the syndrome presents the unique combination of dyspnea and clinical manifestations of asphyxia and that roentgenograms demonstrate good pulmonary aeration. This combination is followed by progressive improvement of symptoms and clouding of the lung fields. A prompt, correct diagnosis is vitally important because, in sharp contrast to the treatment of obstructive atelectasis, infants suffering from hyaline membranes should not be laryngoscoped. Since these infants regurgitate easily, they should not be fed. They should be treated with high oxygen concentration, mist, and antibiotics. Infants brought safely through the first four days of life usually survive (fig. 2).

Positive Pressure Pneumothorax.—Pneumomediastinum and pneumothorax occurring independently or in combination are demonstrated well by chest roentgenograms. In the newborn, localized obstructive emphysema is the most frequent cause of either rupture of the visceral

pleura or passage of air along perivascular spaces into the mediastinal tissues.[4] The recognition of the two conditions is valuable so that unnecessary bronchoscopy may be avoided. Furthermore, the relief of a positive pressure pneumothorax is often a lifesaving procedure.

High Tension Cysts.—The recognition of pulmonary cystic disease in the newborn has acquired increasing significance as the skill of the thoracic surgeon has developed. As Caffey comments in his book "Pediatric X-Ray Diagnosis," many lesions having a roentgenologic appearance suggestive of congenital cysts probably represent emphysematous cavities produced by check valve obstruction of a bronchus. But whatever the pathological anatomy, high tension cysts, by displacement of the thoracic viscera, embarrass respiration and circulation and may cause death. Two recent successive issues of THE JOURNAL contained reports vividly emphasizing the importance of prompt recognition and treatment of these cysts. One was a report[5] of the case of an infant in whom dyspnea and cyanosis developed on the seventh day of life. Roentgenograms revealed large cystic cavities filling the right side of the chest and displacing the mediastinum to the left. Symptoms became severer, and the child was submitted to surgery on the ninth day of life. The cysts were found to be confined to the right middle lobe, which was successfully removed. The baby recovered. Another report[6] described an infant who had had intermittent cyanosis from birth. Air-filled spaces in the left side of the chest demonstrated in roentgenograms on the second day of life were misinterpreted, and the infant underwent abdominal exploration for diaphragmatic hernia. Mediastinal shift and respiratory embarrassment progressed and by the 14th day of life, when the correct diagnosis of cystic disease was recognized, the baby was moribund. Thoracotomy was performed at once. The upper portion of the left lung contained the cysts. A simple excision was hurriedly performed, and the child made a good recovery. In the same article, there is another report of a 10-day-old infant with a history of progressive dyspnea and cyanosis from birth. Decompression of cysts demonstrated radiologically by interrib thoracotomy suction had been attempted but had failed to relieve the baby. When the child was 12 days old, a successful right middle lobe resection was performed. We can cite an instance in which a 4-week-old baby with a history of progressive dyspnea since birth was admitted in a moribund condition. Chest films demonstrated pulmonary cysts, tension pneumothorax, and mediastinal shift (fig. 3). An emergency thoracotomy was performed, a cystic right lower lobe was resected, and the infant recovered. Here there is a dramatic opportunity to alter the graph with which we started.

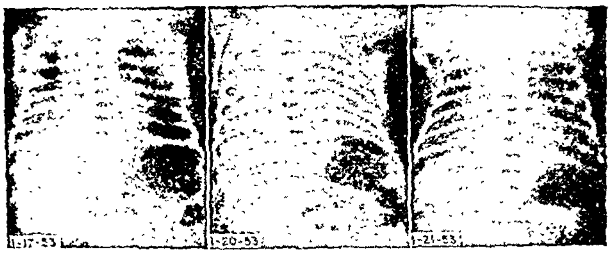

Fig. 2.—Roentgenograms of infant with pulmonary hyaline membrane syndrome; 1/17/53, first day of life, cyanosis and respiratory embarrassment severe; 1/20/53, fourth day, symptoms largely relieved; and 1/21/53, fifth day symptoms absent.

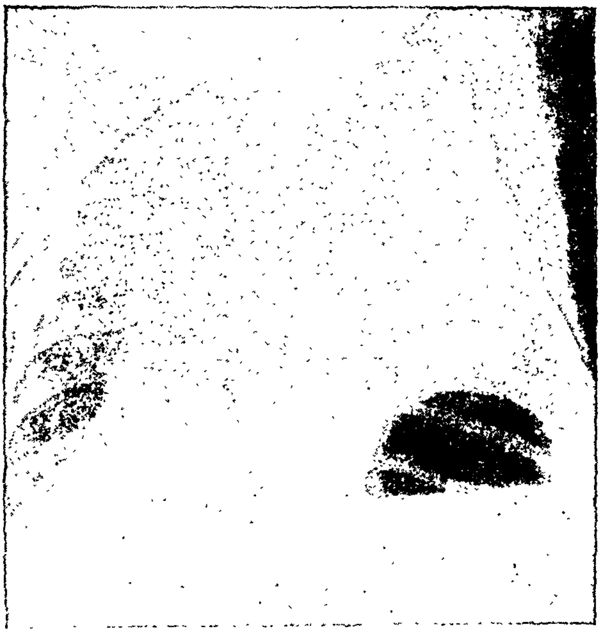

Fig. 3.—Congenital cystic disease of the right lower lobe with positive pressure pneumothorax due to bronchopleural fistulas; emergency lobectomy was followed by excellent recovery.

Diaphragmatic Hernia.—Unless corrected promptly by reduction and surgical repair, a diaphragmatic hernia is apt to cause sudden death. This may be the result of the visceral dislocation or intestinal obstruction with consequent vomiting and aspiration pneumonia. If the infant survives and longer delay is permitted, surgical repair becomes difficult because of the underdevelopment

of the abdominal cavity. Usually thoracic gas shadows arranged in an intestinal pattern make the roentgen diagnosis obvious. Occasionally, a small amount of iodized oil (Lipiodol) must be followed through the gastrointestinal tract. If a thoracic stomach is encountered, a radiopaque medium should always be used to determine the length of the esophagus before surgery is undertaken.

Cardiac Abnormalities.—In considering the contributions of roentgenology to the handling of emergencies in the newborn in which symptoms suggest abnormalities of the contents of the thorax, the discovery of an abnormal cardiac silhouette has been deliberately slighted. Cyanosis and abnormal heart sounds are indications for chest roentgenograms from which useful information is obtained when cardiac abnormalities are present. But since cardiac surgery has as yet no place in the care of the newborn, this subject is mentioned only in passing.

ABDOMINAL MASS

The finding of an abdominal mass other than an enlarged liver or spleen is an emergency in the newborn as well as in older infants. It is an indication for immediate investigation, including roentgen examination.

A soft or cystic mass will probably be found to be due to polycystic kidney disease or hydronephrosis. Abdominal films and excretory pyelograms are usually necessary to establish a diagnosis. While the discovery of polycystic kidney disease is of value only in that it rules out the presence of a treatable condition, recognition of a hydronephrosis is of positive value. Correction by relief of an obstruction or, when necessary, by nephrectomy results in restoration of normal visceral relations in the abdomen and removal of the dangerous threat of infection of the hydronephrosis with subsequent complications. Here, too, is a real opportunity to reduce morbidity and mortality.

Since a solid mass will oftenest be due to a neuroblastoma or a Wilms' tumor, such a discovery is an emergency calling for an investigation of not more than two or three days' duration in preparation for treatment. As neuroblastomas frequently metastasize to the skeleton and Wilms' tumors to the lungs, skeletal and chest roentgen examinations are of prognostic value. Bone marrow studies may reveal invasion by neuroblastoma while the roentgenograms still indicate nothing abnormal. The discovery of metastases should, however, rarely be allowed to alter plans for surgical removal of the primary tumor. Excretory pyelograms may offer roentgen evidence of value in differential diagnosis between the two tumors, but this is of little practical therapeutic value. Pyelograms are of importance in demonstrating the relation, if any, of the abdominal mass to the kidney, and they are a preoperative necessity for proof of the presence of at least one normal, functioning kidney. The treatment of both tumors is prompt surgical excision and roentgen therapy.

Although apparent cures following bone or central nervous system metastases from neuroblastomas occur, they are extremely rare. But results in less advanced cases are encouraging. Farber[7] reported 10 of 40 patients alive three to eight years after treatment, and Wittenborg[8] reported 13 of 23 patients alive three years or longer after treatment, including 6 patients in whom liver metastases were found when the primary tumor was removed. As for the Wilms' tumors, Gross and Neuhauser[9] reported on 18 of 38 patients alive and well two years or longer after surgery and postoperative radiation.

Findings other than the usual may be revealed when an abdominal mass is investigated (fig. 4); but only rarely, except for polycystic kidney disease, is a condition found in which prompt diagnosis and treatment do not result in reduced morbidity and mortality.

DIFFICULT SWALLOWING

Immediate roentgen investigation is indicated when an infant drools excessively or spits up its first feeding. Esophageal atresia, with or without tracheal communication, is usually the cause. There is no need to discuss here the roentgenologic findings in the varieties of esophageal atresia, but it is important to emphasize that the condition is an extreme emergency. Pneumonitis and atelectasis caused by aspiration of food and saliva may develop in the first 24 hours of life. As it, too, may be aspirated, barium suspension should not be used as a contrast medium in the roentgen demonstration of the anatomy. A soft rubber catheter should be inserted to the point of obstruction and then a little iodized oil may be injected. Prompt, accurate diagnosis and immediate surgical establishment of a normal anatomic arrangement are now saving many of these infants.

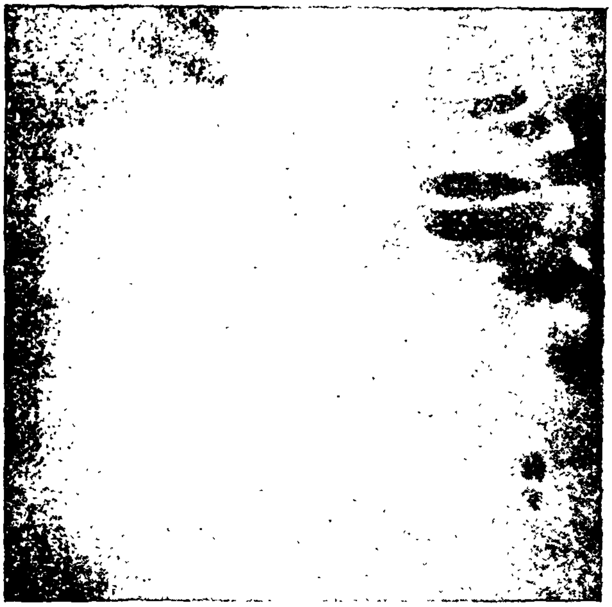

Fig. 4.—Abdominal mass in a newborn found at exploration on second day of life to be an ovarian cyst, which was successfully removed.

VOMITING AND ABDOMINAL DISTENSION

The usual cause of vomiting and abdominal distension in the newborn is obstruction of the small bowel or upper colon. Surgical correction is often lifesaving. Time is of the essence. To quote from Caffey's book again, "There is perhaps no area of pediatric roentgenology where the patient benefits more from accurate diagnosis or where he suffers more from late or inaccurate diagnosis."

Roentgen examination of the abdomen should be carried out immediately after suspicion of intestinal obstruction arises. Though the exact cause of an obstruction may not be determined preoperatively, it is not often that its level cannot be accurately located by the demonstration of distension proximal to the obstruction and collapse distally (fig. 5).

There is no need to discuss the various causes of intestinal obstruction. Our purpose is to emphasize that, because surgical correction is usually possible when undertaken early, prompt investigation of symptoms suggesting obstruction will save lives.

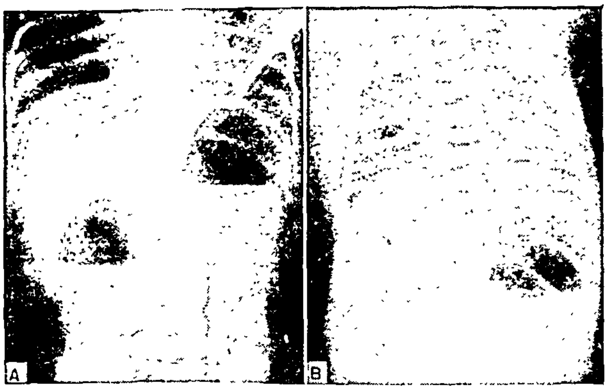

Fig. 5.—Two examples of duodenal obstruction, *A*, due to atresia and, *B*, malrotation of colon and a congenital band.

FAILURE TO PASS MECONIUM

An uncorrected atresia of the lower bowel will, of course, result in abdominal distension and vomiting. But obstruction of the lower bowel should be recognized and corrected before this clinical picture develops. An obvious but frequently overlooked indication for roentgen examination of the newborn is failure to pass meconium or scanty passage. The finding by digital rectal examination of a perforate anus does not remove the necessity of making certain that normal elimination of meconium takes place within a few hours after delivery. Complete atresia may occur above the examining finger anywhere along the colon around to the ileocecal junction and so may stenosis of varying degree.

Unlike atresia of the small bowel in which prompt surgical relief usually saves a life, atresia of the large bowel is seldom survived. Still, the only chance for survival lies in prompt recognition of the difficulty by an alert pediatrician and roentgenologist and immediate surgical intervention.

Roentgen examination is not needed to establish the diagnosis of an imperforate anus, but useful preoperative information can be obtained by taking roentgenograms with an opaque marker on the anal dimple while the baby is inverted. As reported by Wangensteen and Rice in 1930, if the blind rectal pouch is not filled with meconium, gas rises to distend it, permitting accurate measurement of the distance between skin and pouch.[10]

CONCLUSIONS

Since mortality rates in infants under one month old are not declining as rapidly as in infants from 2 to 12 months old, special emphasis should be placed on care of the newborn. Successful treatment of the newborn depends to an unusual degree on quick action.

The roentgenologist can make important contributions to the solution of problems arising in the newborn. Free use of his assistance and close cooperation between pediatrician and roentgenologist is necessary to optimum success in achieving prompt, accurate diagnosis followed by prompt, skillful treatment.

Trends in Authorship.—A major trend in the organization of science during the past two decades has been an evolution away from the individual investigator in favor of research teams. Accompanying this trend, scientific publications have become afflicted with an increasing tendency towards multiple authorship of papers. Almost any scientific journal will reveal this affliction. . . . Is this trend necessary or desirable?

At the risk of being presumptuous, we would define the requisites for authorship of a scientific paper as being "the contribution of creative thinking to the advancement of science." Creative thinking assumes (or at least should assume) its greatest importance in the design of an experiment. How many creative minds contribute to the design of the usual experiment? No data are available and generalizations are hazardous, but it seems a reasonable guess that a distinct majority of experimental designs are the fruit of a single creative mind. There are certainly some instances where two or three individuals, who have worked as colleagues for a significant length of time, can design experiments on the basis of discussions in which there was mutual participation. But how often does the basic design of an experiment represent the product of six to eight individuals thinking in unison? . . .

The practical difficulties created by multiple authorship are obvious. Indexing and bibliographic services represent one of the most difficult problems in the structure of modern science. Whether one considers a large indexing agency or an individual investigator compiling a bibliography, multiple authorship necessitates an extravagant expenditure of valuable time and effort, which might otherwise have been devoted to more constructive endeavors.

Of even greater importance is the degrading effect that multiple authorship has upon the meaning of authorship. It would seem safe for the reader to assign a significant degree of credit to the author's name that appears first. In some instances, the reader also may be able to identify the name of the senior investigator in the laboratory of origin, and rightly or wrongly, assign him some credit for the publication. What of the rest? Just what is the reader supposed to deduce from the fact that John Doe was the seventh out of eight authors? This deduction becomes all the more difficult if the reader discovers that the work reported could easily have been accomplished by two competent investigators in two or three months' time.—Robert S. Alexander, *Circulation Research*, a Journal of the American Heart Association, July, 1953.

SURGERY BY DIRECT VISION IN THE OPEN HEART DURING HYPOTHERMIA

Henry Swan, M.D., Irvin Zeavin, M.D., S. Gilbert Blount Jr., M.D.
and
Robert W. Virtue, M.D., Ph.D., Denver

The heart for centuries was suspected of being a delicate organ; the slightest injury was said to be uniformly fatal. Both the great Billroth and Sir Stephen Paget decreed the organ to lie outside the domain of possible surgery. Yet in reality the heart is a compact muscular organ that, by virtue of highly specialized intrinsic properties, functions continuously throughout the lifetime of the individual. It has an extraordinary capacity to adjust to the changing needs of body circulation. Its inner compulsion toward perpetual function is one of the most critical aspects of the life drive of individuals and species. Only when poisoned or deprived of its flow of nutrient requirements will this persistent organ lie still or lose itself in the quivering death of disorganized activity. A great ability to withstand trauma and to adjust to the stresses imposed by intrinsic disease emphasizes its essential vitality. Given half a chance, the heart will beat.

In the period from 1895 to 1913, Di Vecchio, Haecker, Schepelmann, Elsberg, and Carrel, as well as many others, showed in the experimental laboratory that the heart could withstand surgical trauma and that many complex operative procedures could be performed with relative safety. The main principles of cardiac surgery were well demonstrated and established. The medical tradition of centuries, however, could not be so easily set aside—the heart was delicate and should not be touched! Accordingly, for 25 years the treatment of acute trauma was the only clinical application of this knowledge. In 1938, an event of great import occurred. Pediatrician John Hubbard, of Boston, requested Robert Gross to operate on a child suffering from a patent ductus arteriosus. The successful repair of this congenital "heart" lesion provided the stimulus that has since resulted in the general recognition that the heart is not unique among the organs of the body: it is amenable to surgical therapy.

REVIEW OF SURGICAL PROCEDURES

For the past 15 years in the surgical laboratories and clinics both in the United States and abroad, the principles underlying cardiac surgery have been reexplored and the human application of these techniques has been gradually expanded. In almost all instances, however, these operations have been performed by closed methods; that is to say, the maneuvers within the heart have been done blindly, guided only by the "feel" of the palpating finger. This type of procedure, while often effective, is at best a compromise. To obtain an unimpeded view of the operative field is a fundamental principle of surgery. Adequate exposure for direct vision is an essential component of every safe surgical procedure. In this regard, the interior of the heart has offered some special technical difficulties. Operations on the pericardium, neighboring great vessels, or the exterior of the heart chambers can be easily visualized. The necessity of maintaining circulation during operative maneuvers inside the heart, however, has led investigators to seek the solution of this interesting problem down two separate avenues of study.

The first and more obvious method, of course, was to provide a mechanical pump to furnish the driving force for the blood and then to remove temporarily the heart from the circulation. Either a single pump or two pumps in association with an oxygenator (the animal's own lung, a homologous lung, or a mechanical device) could be utilized, depending on whether one wished to open one or both sides of the heart and depending on whether defects existed in the cardiac septums. This approach to the problem has been vigorously pursued in many laboratories, and recently a few clinical applications have been made.

The technical difficulties associated with this method are great. The instruments are costly and complex and require many skilled persons to use them. A major operative procedure is required to attach the machine to, and later remove it from, the patient's circulatory system, necessarily adding to the magnitude of the total operation and to the postoperative morbidity. The blood of the patient must be heparinized and its capacity to clot later restored with protamine. Overloading of the circulation must be avoided. Hemolysis and air embolism are hazards. Blood flows from the coronary vein into the right auricle and obscures the operative field unless special suction techniques are applied to the sinus. Even so, blood from the thebesian veins on the right and blood from the bronchial artery, via the pulmonary veins, on the left, appear to constitute inescapable flows. At its very best, then, the pump-oxygenators have not yet produced a dry field in which to operate, although the degree of blood flow may be compatible with intermittent visual operative maneuvers. The solutions to many of these problems associated with extracorporeal circulations have been found; others will also be solved; but the inherent characteristics of the technique seem unlikely to change. These adverse characteristics are (1) its complexity and expense, (2) the material increase in the magnitude of operation, and (3) its failure to provide a dry field for operation.

The other avenue of approach to the open heart has been the attempt to lower the metabolism of the patient until circulation can be interrupted for periods of time long enough to allow deliberate and extensive intracardiac maneuvers. It must be remembered that interruption of circulation experimentally was early utilized by Haecker, Schepelmann, and Carrel, and its limitations were explored. In the normal animal, two to three min-

utes appeared to be the maximum allowable time before cardiac or cerebral damage occurred. This technique has recently been used clinically in a few instances,[1] but the need for longer periods of exposure has sharply limited the magnitude of the procedures that could be performed.

To Bigelow [2] and Boerema [3] must go the credit for the conception and demonstration that general hypothermia can be employed to allow cessation of circulation for as long as fifteen minutes in the dog. Since their initial reports, study of the modality of cold has been made in many laboratories. The risks appeared to be high when cooling was associated with interrupted circulation and the open heart. In Bigelow's original series, only 15% of the dogs survived. In the later studies of Lewis and Taufic [4] and of Cookson and co-workers,[5] the mortality was better but still high. The lethal complications were primarily related to two phenomena: ventricular fibrillation and coronary air embolism. To make the use of hypothermia safe for open cardiac procedures, these two complications must be effectively prevented or managed. Unfortunately, in one clinical trial made prior to the series reported herewith, the mortality was high (about 73%).[6] Much of this mortality was due to the desperate nature of the lesions treated, but some was due to the complications of hypothermia with arrest of circulation. In another series, successful closure of interauricular septal defect was achieved in three of six patients.[7]

EXPERIMENTAL STUDY

On the basis of extensive experimental evidence, together with clinical experience in 15 patients, we believe that hypothermia in association with cessation of circulation may now be performed with a degree of safety that warrants a more extensive clinical trial. In our standard experimental situation, a dog was anesthetized with veterinary pentobarbital (Nembutal) and cooled in ice water to a temperature of 20 to 25 C. Thoracotomy was performed; flow of blood into the heart was occluded for 15 minutes, during which time a right auricular cardiotomy was performed. No other pharmaceutical agents were employed. Artificial respiration was performed by means of a mechanical respirator with oxygen via an endotracheal tube. After operation the animal was warmed in water at 45 C. A great variety of physiological variables were studied with the hope of unearthing changes that might be related to the incidence of ventricular fibrillation. This work has been reported elsewhere.[8] In essence, however, two changes in body constants appeared related to fibrillation.

The first change was in the concentration of carbon dioxide in the blood (and probably the tissues). On the basis of our work together with that of others,[9] it appeared likely that a sudden fall in carbon dioxide from an abnormally high level toward normal was a fibrillatory stimulus in the dog. By means of hyperventilation to control carbon dioxide accumulation (deliberate respiratory alkalosis) the incidence of ventricular fibrillation in the experimental animal was reduced to a level of about 8%.

The second change was found to be a shift in the locus of potassium. During cooling and hyperventilation a fall in the potassium level in the serum was observed. The exact significance of this change in terms of ventricular fibrillation was not understood, but the well-known importance of this ion in relation to cardiac rhythm led us to investigate the use of potassium as a defibrillatory agent. Previously, in our hands, the use of electric shock had been entirely ineffective as a means of resuscitation of ventricular fibrillation in the hypothermic animal. We now found, however, that by means of a potassium chloride solution injected into the coronary circulation we could routinely defibrillate the cold dog's heart and restore normal rhythm.

On the basis of these two phases of the study we felt that ventricular fibrillation complicating hypothermia could be largely prevented; even if it occurred, an effective means of resuscitation was available. The other chief source of worry was related to the prevention of coronary air embolism. Extremely small volumes of air entering the coronary arteries are capable of causing myocardial ischemia and death. If the cardiac septums are intact and air enters the right side of the heart, a considerable volume may escape into the pulmonary circulation without lethal effect. Air admitted directly into the left side of the heart or indirectly via a right-to-left opening, such as a septal defect or pulmonary arteriovenous fistula, constitutes an immediate threat to life even if small amounts should escape into the aorta. For this reason, great care must be exercised to prevent this occurrence during open cardiac operations. On the basis of experience with the experimental creation of auricular septal defects, with the use of an open approach through the right auricle in the warm animal, a technique was developed to prevent this catastrophe.[10] Accordingly, in both our experimental and our clinical experience using hypothermia, this complication did not occur.

Surgeons who have had the opportunity to watch valvular function in the open beating heart are impressed with the dual phase of the act of closure of the atrioventricular valves. The first phase appears to be muscular and involves an actual narrowing of the ring at the base of the valve. The second phase is hydrodynamic and re-

quires the presence of sufficient fluid within the ventricle to swing the valve leaflets into the position of effective closure. If the ventricle is filled with air, the second phase does not occur, and the valve remains partially open. Under these circumstances, the ventricle develops no head of pressure to open the outflow valves and there is no forward propulsion of either fluid or air; the aortic and pulmonary valves remain closed.

The importance of these observations in terms of air embolism to coronary arteries is obviously great. Air embolism is unlikely to occur during the period when the heart is open. The dangerous moment occurs immediately after closure of the myocardial incision and the return of blood flow. Air trapped in the heart may now be propelled forward into the peripheral or pulmonary circulations. One of the prime means of prevention, therefore, is to remove all air from the heart before closure of the myocardial incision.

The technique evolved may be described as follows. Inflow of blood into the heart is stopped by occlusion of the venae cavae. About one minute is allowed for the beating heart to partially empty itself and the pulmonary circuit. A noncrushing clamp is now placed across the aorta and pulmonary arteries at their point of exit from the ventricles. It is our intent that this clamp should actually occlude the orifices of the coronary arteries as an added means of precaution. That it does so has been demonstrated experimentally by dye injection techniques. Movement of fluid through the exit valves of course ceases at this moment. The heart is now opened, allowing the residual blood to escape and air to enter. The operative procedure is performed within the allotted time limit. Just before closure of the heart incision, the chest cavity is rapidly flooded with Ringer's solution until the entire heart lies under water. As it beats, the air escapes through the cardiac incision that lies uppermost as the Ringer's solution fills the chambers. After a few beats, it can be clearly seen that no more air is bubbling up from the heart. A second noncrushing clamp is then applied (under water) to the cardiotomy incision, closing the heart. The clamp across the aorta and pulmonary artery is now removed. The superior vena cava is released and blood flow allowed to resume. After about 30 to 60 seconds, when the heart seems to be tolerating its work load again, the inferior vena cava is released and total circulation is resumed. The cardiotomy may now be closed with deliberation. It is important not merely to try to fill the heart with Ringer's solution but to completely immerse the heart in the solution, just as one would submerge a sponge in a bucket.

REPORT OF CASES

CASE 1.—The patient was an 11-year-old cyanotic white boy who weighed 74 lb. (33.6 kg.). The clinical diagnosis of isolated pulmonic stenosis with patent foramen ovale was confirmed by catheterization. On Jan. 9, 1953, hypothermia was induced with the patient under thiopental (Pentothal)-cyclopropane-ether anesthesia. After 37 minutes, when his body temperature was 34 C, he was removed from the ice water. His lowest temperature was 28 C. A standard transventricular pulmonary valvulotomy was accomplished without circulatory occlusion. All observers agreed that the heart was unusually stable throughout the procedure. The patient had an uncomplicated convalescence.

CASE 2.—A 12-year-old white girl, who weighed 60 lb. (27.2 kg.), had cyanotic congenital heart disease due to transposition of the great vessels with an interauricular septal defect. A previous shunt operation had been done four years previously with improvement but had closed during the preceding year. At operation on June 9, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether. After 35 minutes she was removed from the ice water, with a body temperature of 31 C. Her lowest temperature was 26 C. An intrapericardial anastomosis between the ascending aorta and right pulmonary artery was accomplished without arrest of circulation. The heart was very stable throughout. The patient had an uneventful convalescence.

CASE 3.—The cyanotic congenital heart disease of an 8-year-old white boy, who weighed 63 lb. (28.6 kg.) was confirmed by catheterization to be isolated valvular pulmonic stenosis. At operation on Feb. 19, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 44 minutes he was removed from the ice water, with a body temperature of 39 C. His lowest temperature was 25.2 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 7.5 minutes. Partial excision of the stenosed pulmonic valve was accomplished under direct vision through an incision in the pulmonary artery. Auricular fibrillation occurred during cooling but disappeared on rewarming to 27 C. The patient had an uneventful convalescence.

CASE 4.—The patient was a 7-year-old white boy who weighed 51 lb. (23.1 kg.). Cyanotic congenital heart disease was diagnosed as probable infundibular pulmonic stenosis associated with tetralogy of Fallot. Hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 37 minutes he was removed from the ice water, with a body temperature of 30 C. His lowest temperature was 23.6 C. Circulatory arrest was accomplished by complete cardiac inflow tract occlusion for 2.1 minutes. The patient was found to have pulmonic valvular stenosis as part of the tetralogy. Half of the stenotic valve was excised under direct vision. Auricular fibrillation occurred during cooling and disappeared when the patient was rewarmed to 26.5 C. Convalescence was uneventful.

CASE 5.—The cyanotic congenital heart disease of an 8-year-old white girl, who weighed 66 lb. (29.9 kg.), was established by catheterization to be isolated valvular pulmonic stenosis. At operation on March 10, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 39 minutes she was removed from the ice water, with a body temperature of 30 C. Her lowest temperature was 25.7 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 2.5 minutes. Pulmonic valvuloplasty by incision in three places was performed under direct vision. Auricular fibrillation occurred and disappeared when the patient was rewarmed beyond 26 C. Convalescence was uneventful.

CASE 6.—The patient was a 9-year-old white boy who weighed 66 lb. (29.9 kg.). The clinical diagnosis of isolated pure pulmonic stenosis was confirmed by catheterization. At operation on April 14, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether. After 35 minutes he was removed from the ice water, with a body temperature of 30.8 C. His lowest temperature was 23.7 C. Circulatory arrest was accomplished by complete cardiac inflow tract occlusion for 2.5 minutes. Pulmonic valvuloplasty by incision in three places was performed under direct vision. Auricular fibrillation occurred and disappeared on rewarming the patient beyond 26 C. Convalescence was uneventful.

CASE 7.—A 26-year-old white woman who weighed 104 lb. (47.2 kg.) had suffered progressive disability from a large interatrial septal defect confirmed by catheterization on two occasions. At operation on April 15, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 77 minutes she was removed from the ice water, with a body temperature of 29 C. Her lowest temperature was 22.3 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 7.5 minutes. The large interatrial septal defect was closed with direct suture. Auricular utes appeared to be the maximum allowable time before cardiac or cerebral damage occurred. This technique has recently been used clinically in a few instances,[1] but the need for longer periods of exposure has sharply limited the magnitude of the procedures that could be performed.

To Bigelow [2] and Boerema [3] must go the credit for the conception and demonstration that general hypothermia can be employed to allow cessation of circulation for as long as fifteen minutes in the dog. Since their initial reports, study of the modality of cold has been made in many laboratories. The risks appeared to be high when cooling was associated with interrupted circulation and the open heart. In Bigelow's original series, only 15% of the dogs survived. In the later studies of Lewis and Taufic [4] and of Cookson and co-workers,[5] the mortality was better but still high. The lethal complications were primarily related to two phenomena: ventricular fibrillation and coronary air embolism. To make the use of hypothermia safe for open cardiac procedures, these two complications must be effectively prevented or managed. Unfortunately, in one clinical trial made prior to the series reported herewith, the mortality was high (about 73%).[6] Much of this mortality was due to the desperate nature of the lesions treated, but some was due to the complications of hypothermia with arrest of circulation. In another series, successful closure of interauricular septal defect was achieved in three of six patients.[7]

EXPERIMENTAL STUDY

On the basis of extensive experimental evidence, together with clinical experience in 15 patients, we believe that hypothermia in association with cessation of circulation may now be performed with a degree of safety that warrants a more extensive clinical trial. In our standard experimental situation, a dog was anesthetized with veterinary pentobarbital (Nembutal) and cooled in ice water to a temperature of 20 to 25 C. Thoracotomy was performed; flow of blood into the heart was occluded for 15 minutes, during which time a right auricular cardiotomy was performed. No other pharmaceutical agents were employed. Artificial respiration was performed by means of a mechanical respirator with oxygen via an endotracheal tube. After operation the animal was warmed in water at 45 C. A great variety of physiological variables were studied with the hope of unearthing changes that might be related to the incidence of ventricular fibrillation. This work has been reported elsewhere.[8] In essence, however, two changes in body constants appeared related to fibrillation.

The first change was in the concentration of carbon dioxide in the blood (and probably the tissues). On the basis of our work together with that of others,[9] it appeared likely that a sudden fall in carbon dioxide from an abnormally high level toward normal was a fibrillatory stimulus in the dog. By means of hyperventilation to control carbon dioxide accumulation (deliberate respiratory alkalosis) the incidence of ventricular fibrillation in the experimental animal was reduced to a level of about 8%.

The second change was found to be a shift in the locus of potassium. During cooling and hyperventilation a fall in the potassium level in the serum was observed. The exact significance of this change in terms of ventricular fibrillation was not understood, but the well-known importance of this ion in relation to cardiac rhythm led us to investigate the use of potassium as a defibrillatory agent. Previously, in our hands, the use of electric shock had been entirely ineffective as a means of resuscitation of ventricular fibrillation in the hypothermic animal. We now found, however, that by means of a potassium chloride solution injected into the coronary circulation we could routinely defibrillate the cold dog's heart and restore normal rhythm.

On the basis of these two phases of the study we felt that ventricular fibrillation complicating hypothermia could be largely prevented; even if it occurred, an effective means of resuscitation was available. The other chief source of worry was related to the prevention of coronary air embolism. Extremely small volumes of air entering the coronary arteries are capable of causing myocardial ischemia and death. If the cardiac septums are intact and air enters the right side of the heart, a considerable volume may escape into the pulmonary circulation without lethal effect. Air admitted directly into the left side of the heart or indirectly via a right-to-left opening, such as a septal defect or pulmonary arteriovenous fistula, constitutes an immediate threat to life even if small amounts should escape into the aorta. For this reason, great care must be exercised to prevent this occurrence during open cardiac operations. On the basis of experience with the experimental creation of auricular septal defects, with the use of an open approach through the right auricle in the warm animal, a technique was developed to prevent this catastrophe.[10] Accordingly, in both our experimental and our clinical experience using hypothermia, this complication did not occur.

Surgeons who have had the opportunity to watch valvular function in the open beating heart are impressed with the dual phase of the act of closure of the atrioventricular valves. The first phase appears to be muscular and involves an actual narrowing of the ring at the base of the valve. The second phase is hydrodynamic and requires the presence of sufficient fluid within the ventricle to swing the valve leaflets into the position of effective closure. If the ventricle is filled with air, the second phase does not occur, and the valve remains partially open. Under these circumstances, the ventricle develops no head of pressure to open the outflow valves and there is no forward propulsion of either fluid or air; the aortic and pulmonary valves remain closed.

REPORT OF CASES

Case 1.—The patient was an 11-year-old cyanotic white boy who weighed 74 lb. (33.6 kg.). The clinical diagnosis of isolated pulmonic stenosis with patent foramen ovale was confirmed by catheterization. On Jan. 9, 1953, hypothermia was induced with the patient under thiopental (Pentothal)-cyclopropane-ether anesthesia. After 37 minutes, when his body temperature was 34 C, he was removed from the ice water. His lowest temperature was 28 C. A standard transventricular pulmonary valvulotomy was accomplished without circulatory occlusion. All observers agreed that the heart was unusually stable throughout the procedure. The patient had an uncomplicated convalescence.

Case 2.—A 12-year-old white girl, who weighed 60 lb. (27.2 kg.), had cyanotic congenital heart disease due to transposition of the great vessels with an interauricular septal defect. A previous shunt operation had been done four years previously with improvement but had closed during the preceding year. At operation on June 9, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether. After 35 minutes she was removed from the ice water, with a body temperature of 31 C. Her lowest temperature was 26 C. An intrapericardial anastomosis between the ascending aorta and right pulmonary artery was accomplished without arrest of circulation. The heart was very stable throughout. The patient had an uneventful convalescence.

Case 3.—The cyanotic congenital heart disease of an 8-year-old white boy, who weighed 63 lb. (28.6 kg.) was confirmed by catheterization to be isolated valvular pulmonic stenosis. At operation on Feb. 19, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 44 minutes he was removed from the ice water, with a body temperature of 39 C. His lowest temperature was 25.2 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 7.5 minutes. Partial excision of the stenosed pulmonic valve was accomplished under direct vision through an incision in the pulmonary artery. Auricular fibrillation occurred during cooling but disappeared on rewarming to 27 C. The patient had an uneventful convalescence.

Case 4.—The patient was a 7-year-old white boy who weighed 51 lb. (23.1 kg.). Cyanotic congenital heart disease was diagnosed as probable infundibular pulmonic stenosis associated with tetralogy of Fallot. Hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 37 minutes he was removed from the ice water, with a body temperature of 30 C. His lowest temperature was 23.6 C. Circulatory arrest was accomplished by complete cardiac inflow tract occlusion for 2.1 minutes. The patient was found to have pulmonic valvular stenosis as part of the tetralogy. Half of the stenotic valve was excised under direct vision. Auricular fibrillation occurred during cooling and disappeared when the patient was rewarmed to 26.5 C. Convalescence was uneventful.

Case 5.—The cyanotic congenital heart disease of an 8-year-old white girl, who weighed 66 lb. (29.9 kg.), was established by catheterization to be isolated valvular pulmonic stenosis. At operation on March 10, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 39 minutes she was removed from the ice water, with a body temperature of 30 C. Her lowest temperature was 25.7 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 2.5 minutes. Pulmonic valvuloplasty by incision in three places was performed under direct vision. Auricular fibrillation occurred and disappeared when the patient was rewarmed beyond 26 C. Convalescence was uneventful.

Case 6.—The patient was a 9-year-old white boy who weighed 66 lb. (29.9 kg.). The clinical diagnosis of isolated pure pulmonic stenosis was confirmed by catheterization. At operation on April 14, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether. After 35 minutes he was removed from the ice water, with a body temperature of 30.8 C. His lowest temperature was 23.7 C. Circulatory arrest was accomplished by complete cardiac inflow tract occlusion for 2.5 minutes. Pulmonic valvuloplasty by incision in three places was performed under direct vision. Auricular fibrillation occurred and disappeared on rewarming the patient beyond 26 C. Convalescence was uneventful.

Case 7.—A 26-year-old white woman who weighed 104 lb. (47.2 kg.) had suffered progressive disability from a large interatrial septal defect confirmed by catheterization on two occasions. At operation on April 15, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 77 minutes she was removed from the ice water, with a body temperature of 29 C. Her lowest temperature was 22.3 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 7.5 minutes. The large interatrial septal defect was closed with direct suture. Auricular fibrillation occurred and disappeared when the patient was rewarmed beyond 26.5 C. She was given a smaller transfusion than would have been usual in such an operation because of fear of heart failure. Shock occurring in the recovery room was successfully combated with 1,500 cc. of blood. Convalescence was slow, with shifting arrhythmias that complicated her course. Two months later the heart was smaller, and a great increase in exercise tolerance had occurred.

Case 8.—The cyanotic congenital heart disease of a 10-year-old white boy, who weighed 70 lb. (31.8 kg.), was established as tetralogy of Fallot by catheterization. At operation on April 21, 1953, hypothermia was induced with the patient under cyclopropane-ether anesthesia. After 45 minutes he was removed from the ice water, with a body temperature of 31 C. His lowest temperature was 24.6 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 8.5 minutes. An infundibular stenosis was excised under direct vision. An anomalous coronary artery frustrated attempt at a larger ventriculotomy to repair the interventricular septal defect. Cardiac arrest occurred during the operation but responded immediately to massage. Auricular fibrillation occurred during cooling and disappeared on rewarming the patient. Convalescence was uneventful.

Case 9.—A 6-year-old white girl, who weighed 41 lb. (18.6 kg.), had suffered progressive disability from a large interatrial septal defect proved by catheterization. At operation on May 5, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 40 minutes, she was removed from the ice water, with a body temperature of 29 C. Ventricular fibrillation was noted four minutes later, and cardiac massage was instituted rapidly. Defibrillation was performed with 0.5 mEq. of potassium chloride perfused into the coronary arteries. Her lowest temperature was 22.6 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for five minutes. A large interatrial septal defect was closed by direct suture. Cardiac arrest occurred after partial closure of the pericardium. Massage and intracardiac injection of 2 cc. of 2% calcium chloride were effective in restoring normal rhythm. Convalescence was uneventful except for temporary bilateral peroneal palsy of unknown cause.

Case 10.—Isolated pulmonic valvular stenosis without cyanosis was confirmed in a 3-year-old white girl, who weighed 34 lb. (15.4 kg.), by catheterization. On June 12, 1953, hypothermia was induced with the patient under vinyl ether (Vinethene) and ethyl ether anesthesia. After 23 minutes she was taken from the ice water, with a body temperature of 30 C. Her lowest temperature was 25.5 C. Circulatory arrest was accomplished by complete cardiac inflow occlusion for 2.17 minutes. Incision of the thick stenosed pulmonic valve was done in two places under direct vision, forming a bicuspid valve. The patient had an uneventful convalescence.

Case 11.—The patient was a 4-year-old boy who weighed only 26 lb. (11.8 kg.). His interauricular septal defect with tricuspid regurgitation had produced a very large heart bordering on failure, in spite of digitalis therapy during the past two years. At operation on June 18, 1953, hypothermia was induced with vinyl ether-ethyl ether anesthesia. After 19 minutes the patient was removed from the ice water, with a body temperature of 29 C. His lowest temperature was 21.5 C. Technical repair of the septal defect was accomplished satisfactorily with seven minutes of inflow tract occlusion. The heart went into standstill during occlusion and shortly afterward into ventricular fibrillation. The patient was warmed to 33 C, while cardiac massage maintained the circulation. The ventricles were defibrillated with potassium. The beat, however, was never vigorous, and the patient died with a dilated failing myocardium.

Case 12.—The frail stature of a 6-year-old boy, who weighed 40 lb. (18.1 kg.), was due to a large interauricular septal defect, although he had never been in frank heart failure. At operation on June 26, 1953, hypothermia was induced with the patient under thiopental-cyclopropane-ether anesthesia. After 35 minutes he was removed from the ice water, with a body temperature of 28 C. His lowest temperature was 25.5 C. A large interatrial septal defect was sutured under direct vision during occlusion of circulation lasting 6 minutes 15 seconds. Auricular fibrillation reverted to sinus rhythm on return of circulation. The patient's postoperative course was uneventful.

Case 13.—The patient was a 3-month-old boy who was suffering acute heart failure associated with intense cyanosis. His condition improved with digitalis and oxygen, but three days later jaundice developed, thought to be hepatic in origin. On June 26, 1953, because of his large heart and his failure to improve, he was operated on, with a diagnosis of possible pulmonary valvular stenosis. Hypothermia was induced rapidly with the patient under thiopental-ether anesthesia. After 11 minutes he was removed from the ice water, with a body temperature of 30.8 C. His lowest temperature was 25.6 C. Exploration revealed idiopathic pulmonary hypertension. No therapeutic procedure was attempted. Immediate recovery was satisfactory, but the patient subsequently died of his cardiac malformation.

Case 14.—The cyanotic heart disease of a 28-year-old white mother of 2 children had caused progressive disability for the preceding two years. Two months before admission a right hemiplegia had occurred. Clinical diagnosis of tetralogy of Fallot was confirmed by angiocardiographic demonstration of infundibular pulmonic stenosis. At operation on July 1, 1953, cardiac standstill occurred after induction and intubation but before cooling was begun. Cardiac resuscitation was accomplished after 2 minutes 10 seconds by thoracotomy and massage. The wound was closed tightly with mattress sutures, and the patient then cooled in ice water for 47 minutes to 31 C. Her lowest temperature was 25.5 C. Cardiac arrest again occurred as the chest was being prepared for draping. The previous wound was rapidly reopened and the heart beat restored by massage at 1 minute 10 seconds. From this point on, the heart beat was remarkably stable. With circulatory arrest lasting five minutes, a tight infundibular stenosis was excised under direct vision through a right ventriculotomy. No attempt was made to close a very small interventricular septal defect. Immediately after the patient's recovery from anesthesia, cyanosis disappeared. The postoperative course was uneventful.

Case 15.—The patient was a 20-month-old girl who weighed 18 lb. (8.2 kg.). Cyanosis during an upper respiratory infection led to the diagnosis of pulmonic valvular stenosis with patent foramen ovale. Operation was performed on July 9, 1953. Hypothermia was induced with the patient under thiopental-ether anesthesia. After 24 minutes she was removed from the ice water, with a body temperature of 31 C. Her lowest temperature was 27 C. Via an incision in the pulmonary artery, plastic revision and partial excision of the stenotic pulmonary valve was performed during circulatory arrest lasting 3 minutes 50 seconds. The patient's operative course was uneventful, and her immediate recovery was quite satisfactory.

COMMENT

These specific operations were chosen deliberately for the initial experience with human hypothermia, because the existing operations for the diseases treated have left much to be desired. As experience has accumulated in various clinics, it has become increasingly clear that the transventricular incision and dilatation of the stenosed pulmonary valve has given very disappointing objective results.[11] It is true the immediate clinical results are excellent. But surgeons who have studied, by actual measurement, the residual right ventricular pressure weeks or months following operation in these same patients have found a disturbing number in whom this pressure is still markedly elevated, that is, a systolic pressure of 70 mm. Hg or more. This is a level approximately three times normal, and, although it is lower than it was preoperatively, it is still pathologically elevated. One cannot predict a normal life span for such a patient. It seems desirable, therefore, to attempt a more complete plastic revision of the valve, a maneuver easily made possible by the direct vision technique.

S., and Hill, E.: Pulmonary Valvuloplasty Under Direct Vision: Aid of Mechanical Right Heart, read before the American Association of Thoracic Surgery, San Francisco, March, 1953. Humphreys, G. H.; Powers, S. R.; Fitzpatrick, H. F., and Lanman, B. M.: Pulmonary Valvular Stenosis: Clinical and Physiologic Studies of 25 Cases Treated by Valvulotomy, read before the Meeting of Society for Vascular Surgery, New York, May, 1953.

Resection of infundibular stenosis blindly with rongeurs has not appealed to many surgeons. Resection of a precise area under direct vision associated with the additional possibility of closing the ventricular septal defect in tetralogy of Fallot offers the potentiality of actually curing the patient of his intracardiac defects. Clearly, if the procedure is feasible and safe, this would be an objective superior to the addition of a shunt. Resection of the stenosis is not unduly difficult, but closure of the septal defect may prove more arduous.

The operations currently available for interauricular septal defects are all blind manipulations and carry a significant operative risk.[12] Certain types of defects, particularly septum primum lesions overlying the valves, are not amenable to treatment by these methods. An open operative approach to this problem seems worthy of trial.

To date, we have used cooling with cessation of circulation primarily in children, only two patients having been adult. There is good experimental evidence that the young tolerate this procedure with greater safety than the older age group. We hope to establish the safety of the procedure in this younger age group before proceeding to expand slowly into adult ranges.

We believe it is desirable to cool the patients as rapidly as possible, perform the procedure, and then warm to near normal temperatures at once. Cardiac irregularities occur with great frequency in these sick hearts at levels below 28 C. Auricular fibrillation, although common in the human patient, is not a matter of great concern, because, in our experience, if it occurs during cooling, a sinus rhythm will always return at approximately the same temperature during rewarming. Ventricular fibrillation has occurred twice but was successfully reverted on both occasions by the use of potassium. In one patient, however, sustained spontaneous beat could not be subsequently obtained, we believe, because of cardiac dilatation and myocardial failure. This was the only operative death in the series.

The importance of an adequate exposure of the heart and great vessels for this type of procedure must be emphasized. It is essential that all sides of the heart, the superior and inferior venae cavae, the ascending aorta and pulmonary artery, and the lung roots be readily reached. For this, in our experience, there is no incision equal to the bilateral transverse sternal-cutting intercostal incision in the fourth interspace. Although long, the incision involves the removal of no part of the thoracic skelton, is well tolerated by the patient, and heals quickly, with minimal postoperative discomfort.[2]

SUMMARY AND CONCLUSIONS

Fifteen patients have undergone cardiac operations while they were in a state of hypothermia, with body temperatures ranging from 21.5 to 26 C. In 13 of these patients, circulation was stopped for periods varying from 2 to 8½ minutes, and the operation was performed in the open heart under direct vision. There was one operative death in this group. The remainder of the patients have had excellent clinical results, save one on whom no therapeutic procedure could be performed.

Hypothermia was induced during anesthesia by immersing the patient in a tub full of ice water; warming was also achieved in the tub with warm water. Speed of cooling depended largely on body build; the less obese patients cooled more rapidly. Prevention of shivering and hyperventilation were very important aspects of the cooling technique. Potassium appeared to be a valuable agent for combating ventricular fibrillation in the cold patient. The prevention of coronary artery air embolism was of great importance and was achieved by a combination of maneuvers, of which one of the most important was complete immersion of the heart in salt solution at the time of closure of the cardiotomy.

Direct vision intracardiac surgery should be further explored and possibly expanded in scope, since cessation of circulation in the presence of hypothermia allows an essentially bloodless field, with reasonable safety for periods up to at least eight minutes. It is surprising how much can be deliberately accomplished in this period of time. Various forms of pulmonic stenosis in nine patients and interauricular septal defects in four have been successfully repaired by this technique. Other stenotic or regurgitant valve lesions and defects of the ventricular septum may also prove to be amenable to therapy.

Living.—It may well be true that we have from necessity directed most of your time to vocational training and that we have not paid much attention to training you how to live. The graciousness of life has perhaps been blurred by the overriding necessity of acquiring efficiency and of keeping abreast of scientific progress. We may thus have given you too little time to cultivate a sense of beauty, to quicken your appreciation, and to improve your discrimination between things which are good and those which are not. That is not necessarily the case, but even if it were, it is fortunately not too late to remedy it. You must not only keep in touch with the literature in your own and related subjects, but you would also be wise to take such interest as you can in literature in general, in music, and in art. History is the great opener of doors and you will find that the history of your own subject will give you an insight into the development of man and his problems, and add interest and colour to your life. Getting a wider knowledge of man and the world he lives in, of his arts and crafts, of his philosophy and religions, and obtaining some acquaintance with the thoughts and ideas of the great scholars and scientists of the past will provide you with a well-furnished mind which, when the emotional side of your life becomes of lessening importance and your work is not the all-in-all that you think it is now, will be a source of comfort and delight.—*Sir Sidney Smith*, valedictory address delivered at the graduation ceremony in the McEwan Hall, Edinburgh, on July 15, 1953, *The Lancet*, Sept. 5, 1953.

MERITS OF THE PRESENT CORONER SYSTEM

STATISTICAL COMPARISON WITH THE MEDICAL EXAMINER SYSTEM

Henry W. Turkel, M.D., San Francisco

Many articles have appeared in recent years, in both lay and professional journals,[1] recommending more widespread use of the medical examiner system of medicolegal investigation. With this stimulus, numerous moves have been made to supplant the coroner system, just as is now occurring in California.

It is felt, however, that many of the conclusions drawn and references made relative to the coroner system are taken from sources long outdated. Issue is often made of the fact that the office of the coroner dates back to the time of Henry IV, and the function of the office in that era is described in considerable detail. This would seem to have little or no bearing in a factual analysis of modern coroners' offices. Repeatedly, the very unfavorable report of the National Research Council is offered as evidence of the inadequacies of the coroner system. This report, the last to deal in facts rather than generalizations, was made in 1928 [2] and enlarged in 1932.[3] Since that report was made 21 years ago, any conclusion drawn from it would have little application in a review of the operation of present-day coroners' offices and should not be permitted to reflect in any present determination of the need for a change.

While the conduct of coroners' offices in some of the large metropolitan centers, in years past, may have warranted a change, which did indeed lead to improvement, there should be evidence showing that any given locality has actual need for such a change before it is undertaken.

SYSTEMS DESCRIBED

Varying somewhat with the local laws, the coroner, or his deputy, investigates the cause and circumstances of all deaths from unnatural causes, such as by violence, injury, or criminal means, or from unknown causes. The coroner may, at his discretion, order autopsies or other scientific procedures. Further, he may subpoena witnesses to appear at an inquest, at which time the facts and events related to the death are recorded. If a crime is suspected by the jury, appropriate criminal proceedings are instituted independently of any other law enforcement agency; thus an accused is brought before a judge.

The medical examiner, similarly subject to variation in local laws, investigates all deaths that occur under the circumstances listed above, and the purposes and goals are the same as those of the coroner.

Minor differences are to be found between the two systems in the mechanics and administration of the medicolegal investigations. There are three main diferences. 1. Medical examiners require that a physician investigate the scene of death, while coroners use trained deputies. 2. The chief medical examiner who directs the activities of his office must be a physician, while coroners who have similar supervisory activities may be laymen. 3. The medical examiner does not hold inquest proceedings; thus he has no direct authority to bring an accused before a judge. He refers his findings to the district attorney who, in turn, may or may not take action according to his own view or wish.

These differences apparently lead to the only major and important difference, that is, the relative effectiveness with which each system reaches the desired end. That end is the discovery of the true cause of death and the administration of justice. Whether a system is or is not accomplishing that end is not a matter for sheer speculation but requires careful statistical evaluation. This study, based on current statistics, compares California coroner jurisdictions with various of the medical examiner jurisdictions. It may serve as a guide in pointing out the need and available methods for critical review of the existing program in any area contemplating a change.

COMPARISON OF AUTOPSY RATES

Recently, the Council on Medical Education and Hospitals of the American Medical Association has directed [4] that "No hospital will be approved for intern training which does not maintain an autopsy rate of at least 25% of its deaths." The council continues, "The necropsy rate has come to be recognized as an index of the scientific interest of the medical staff."

The quality and thoroughness, as well as the scientific interest, in medicolegal investigation is similarly reflected by the percentage of autopsies done to correctly establish the cause of death. This is particularly true if one considers that all deaths requiring medicolegal investigation occur under doubtful or unknown circumstances, whereas in hospitals there is almost always some study before death occurs.

Table 1 is taken from statistics available as far back as 1949. While the figures from the various communities are not all for the same year, they are for the last available year and are within the period 1949-1952. This is deemed representative, since such figures do not change by more than 1 or 2% from year to year.

Any case falling within the jurisdiction of medicolegal authority has, by definition, a very real element of doubt. It is difficult to conceive that the true cause and all contributory factors in these deaths by violence, injury, or unknown causes can be ascertained when, as in some jurisdictions, in 60 to 80% of these cases the cause of death is established from history and inspection without an autopsy. That in one jurisdiction autopsies were per-

formed to find the correct cause of death in only 3% of these doubtful cases is an almost alarming finding.

Coroners, often laymen, are said perhaps to order more autopsies than are necessary. While they obviously order more, it cannot be said that these are not necessary. Some believe that medical examiners can oftener establish the cause of death without an autopsy because they are physicians and because they go to the scene to inspect the body and surroundings. We know, however, that every physician knows of occasions in which a preliminary opinion, made after considerable antemortem study, was proved wrong at autopsy. It is doubtful that anyone, physician or not, can safely establish the cause of death in a medicolegal case without an autopsy, except in a relatively few instances.

To establish this point exactly, I have utilized the records of the San Francisco coroner's office in which autopsies are performed in 99% of coroner's cases.

§ Personal communication to the author from the Deputy Medical Examiner, Milwaukee County, Wisconsin.
‖ Personal communication to the author from the Chief Medical Examiner, State of Rhode Island.

Five-hundred consecutive cases that fell within the coroner's jurisdiction were reviewed. In 379, death occurred without medical attendance or the physician in attendance was unable to state the cause of death. In the remaining 121, a private or hospital physician was in attendance at the time of death, and he was sufficiently acquainted with the case to offer a final diagnosis. These were nonetheless coroner's cases because (under California law) the physician was not in attendance long enough, the death involved violence or injury, or some suspicious circumstance was apparent to the coroner. Of the 121 cases in which the physician gave the final diagnosis, that diagnosis was incorrect in 54 (45%) of the cases. In fact, in 35 of these 54 cases, the site of the condition causing the death was in an organ or organ system other than that designated by the physician. Examples of incorrect diagnosis would be when death is found at autopsy to be due to pulmonary embolism rather than to pneumonia or when death is due to a subdural hematoma rather than to a spontaneous cerebrovascular accident. Examples of incorrect organ or organ system diagnosis are when death is due to brain tumor instead of coronary occlusion or when death is due to hemoperitoneum following intra-abdominal injury rather than to perforated peptic ulcer.

It is recognized that antemortem studies in these cases are made under such trying circumstances that the errors in diagnosis are not unreasonable or in any way a reflection on the capabilities of the physician. The fact presents itself, however, that, if these same physicians had attempted to arrive at diagnoses without autopsy on the other 379 coroner's cases in question, it would seem certain that the percentage of incorrect diagnoses would be even greater than 45%, since there was usually no antemortem study and the physician would have only the history and an external inspection to rely on. It is doubtful that a medicolegal officer, even though a physician, is a more capable diagnostician than any other physician or that he can, merely by inspection and review of the history, reach correct diagnoses with a significantly smaller percentage of error.

In the light of the foregoing figures, any physician who establishes the cause of death in a medicolegal case, without an autopsy, runs a chance almost half of the time that his diagnosis is in error. Except that they contribute to erroneous vital statistics, the majority of such errors are of relatively little consequence in the ordinary course of events, and the mistakes are safely, although not properly, buried with the body. While the medicolegal officer's mind may rest free in the knowledge that his is the last word and that he is not likely to be questioned, this is false comfort. As long as he relies solely on his judgment of the history and the inspection of the body, he must realize that he will continue to establish the cause of death erroneously in a certain percentage of cases. Not until autopsies are performed in all of these medicolegal cases will he become fully aware of the importance of such thoroughness. Only then can he truly see that great numbers of these errors are not purely academic but that they reflect seriously in the lives and welfare of many persons. Such errors in diagnosis weigh heavily in criminal and legal considerations and can lead to grave mistakes in the administration of justice.

There have been many instances in which all the external evidence and the history gave every justification for presuming a natural death and in which the cause of death was evident from the antemortem signs and symptoms. But, by virtue of routine autopsy, the causes of death in these cases were found not to be natural; some were due to accidents and some to crimes. Often, the need for investigation or criminal prosecution was not recognized until after the autopsy. Had these cases not been discovered by routine autopsy, the errors would never have been noted and the truth would have been buried.

It should be apparent that any case doubtful enough to warrant a medicolegal investigation deserves an autopsy. Autopsy should always be done if there are legal grounds to authorize it. This view is held to assure that crimes or misadventure will not be overlooked and to make certain that anyone who may now or later be suspected of having perpetrated a crime will not be falsely convicted because of inadequate investigation. If the state assumes the right to judge and punish persons for crimes or negligence, it has a far greater obligation to insure that no one is falsely or unjustly punished. No trouble or effort is too great to assure this last point, and no one can be so wise that he unfailingly arrives at a proper conclusion simply by deduction or inspection.

† Coroner or medical examiner cases are those in which the death certificate is signed by the medicolegal authority after he has established the cause of death.

‡ From the individual annual reports published by each of the counties listed.

§ Statistical Report of the State Medical Examiner, City of New York, 1950, and personal communications to the author.

‖ 12th Annual Report of the Department of Postmortem Examiners, State of Maryland, 1950.

¶ Personal communication from the Chief Medical Examiner, State of Rhode Island.

The basic and prime purpose of a medicolegal office is the determination of the true cause of all deaths and the assurance that justice is done. It is also safe to presume that the lower the autopsy rate, the greater the number of gross errors and, therefore, grave injustices and, indeed, the less likely is the office to achieve its prime purpose and objective. Figures on autopsy rates are readily available. While not previously done, they can and should be used as an indication of the proper and satisfactory functioning of medicolegal investigative systems because they offer clear evidence of relative merit.

USE OF LABORATORIES

It is frequently urged that a change to a centrally controlled, statewide system would increase the number of laboratory tests done by making the central state offices available to outlying communities.[5] To weigh this matter, let us examine and compare the extent of utilization of laboratory procedures in California (many of which are done in private laboratories throughout the state) with other jurisdictions using state-operated central laboratories.

By studying table 2, a proper analysis can be gained by comparing one city with another or one rural area with another, since land area served is a vital factor. One should note, therefore, the percentages in San Francisco and New York or, on the other hand, Los Angeles County and the State of Maryland.

It is generally taken for granted that a state-supported medicolegal laboratory is available without specific charge to any authorized public officer requesting its services. One presumes then that it would be very freely used, certainly more than if the public officers had to call on private laboratories on a fee basis. Interestingly enough, the California coroners' jurisdictions, in great part using private laboratory facilities on a fee or contract basis, have availed themselves of laboratory procedures oftener than the medical examiner jurisdictions that use state-supported laboratories. It need not be said, therefore, that a state-operated laboratory will, as a foregone conclusion, be used more frequently.

Similar studies in other states might be equally revealing. It is only after painstaking statistical analysis that an appropriate decision can be reached. Too often in these matters, conclusions have been drawn from generalizations rather than facts, and these conclusions have gained acceptance purely by virtue of repeated public utterance. A more reasonable approach would be to make a study and, thereafter, to support and encourage whichever system is found to actually employ scientific methods most frequently.

Volume of laboratory work is not, in itself, sufficient cause to justify it. There is, however, a relationship between the amount of laboratory work done and the number of positive findings. Table 3 shows the importance of adequate amounts of laboratory work in establishing the cause of death. It can be seen from the third and fifth columns of table 3 that, roughly, the higher the percentage of doubtful cases tested, the higher the percentage of correct causes of death.

It is interesting, for example, that in San Francisco deaths by barbiturate poisoning are approximately four times as frequent (per unit population) as in Maryland. There are no apparent factors such as population, racial differences, or variations in state hypnotic laws that would account for so wide a discrepancy. It will be noted, however, that in San Francisco tests for barbiturates were made approximately four times as often as in Maryland. In fact, there is a sufficiently close relationship between the percentage of cases tested and the number of positive findings that increasing volume of laboratory testing is to be favored.

---

[5] Ford, R.: Medicolegal Investigation of Sudden and Unexplained Deaths, J. A. M. A. 145: 1027-1030 (April) 1951. Gradwohl, R. B. H.: Should the Office of Coroner Be Continued, Ann. West. Med. & Surg. 4: 491-494 (Sept.) 1950.

It is inherent in the nature of his work that a medicolegal authority be suspicious. This attitude of suspicion is a measure of his desire to do his work carefully and thoroughly. These suspicions, when once held, can best be dispelled and a proper finding made by use of appropriate scientific procedure as has been shown here. Thus, an index of the worth of a medicolegal investigative office or system may be determined, again, by an inquiry into the frequency of use of laboratory procedures in establishing causes of death. This has heretofore not been generally done.

AREAS INVOLVED

No state of any great size has undertaken a statewide medical examiner system. New York, with 26 years' experience, has confined its medical examiner system to metropolitan New York City, while the remainder of the state is on local option. Maryland has a statewide system wherein one sees that the autopsy rate in Baltimore is 37%, while in the remainder of the state it is 18%. The state of Maryland (12,000 square miles) is about one-half the size of San Bernardino County in California. If the more rural the area the fewer the autopsies, one might wonder how low the percentage would drop if the Maryland medical examiner system were applied to the 20,000 square miles of San Bernandino County or to the 157,000 square miles of California. The size of the area to be covered by a centrally dominated statewide system is indeed deserving of consideration. The mechanics and function of the coroner system appear to be better adapted to large land areas. This is evidenced by the finding that the autopsy rate in California is at least 2 times and as much as 20 times greater than in areas of medical examiner jurisdiction that cover smaller rural areas and on which statistics were available (table 1). A central controlling state agency, such as a medical examiner system, will not necessarily improve medicolegal investigation, particularly if large land areas are involved. It is quite likely, in fact, that such control would lead to deterioration. It would be worth while to speculate on the reasons.

The medical examiner system requires that investigation at the scene of death be made by a physician. In an area as large as California, for example, it is only with some difficulty that physicians are found who will travel over large counties to do the required autopsies, let alone go beforehand to the scene of every death occurring by violence or injury or under doubtful circumstances. Furthermore, if a physician goes to the scene of death to view the body and then orders an autopsy, he must wait for the body to be moved to some convenient place and then travel to that place, again over great distances, to perform the autopsy. It can be said, and the statistics support, that this tends to markedly increase the number of cases signed out on the basis of history and circumstances and without benefit of autopsy. This is not conducive to impartial scientific investigation into the causes of death.

The medical examiner laws generally direct that autopsies be done by certified pathologists, at least in the larger centers. This is indeed a commendable principle, but one should consider that, after passing statewide legislation enacting such a law (in itself no simple task), one might find the law impossible to fulfill. It would be well for any community contemplating such moves to inquire into the present need and, further, into the practicability of fulfilling the law once it was enacted. The results can be as surprising as they were under the California coroner system in which the following situation was found.

San Francisco has had a physician as coroner for 40 or more years, just as at present. Two of the autopsy surgeons are board certified, and the third is board eligible. The pathologist who reviews autopsy findings by gross and microscopic sections is also board certified. The toxicologist is a physician and has a Ph.D. in pharmacology. Five of the six physicians on the staff are engaged in teaching in their respective fields and in medicolegal courses at the local medical schools. In Los Angeles, where the coroner is a layman, autopsy surgeons are required to be graduates of approved medical schools, to have done an interneship, and to have had at least two years' training in the various fields of pathology or legal medicine. Marin County, across the bay from the two San Francisco medical schools, has a mortician as its coroner. Significantly, 92% of the cases for which he signs the death certificate have had the cause of death established by an autopsy done by his staff of two pathologists, both board certified. Alameda County, also across the bay from the medical schools, has a layman as coroner. He orders all autopsies and laboratory work to be done by certified pathologists. The situation is similar in many nearby counties.

TABLE 3.—*Comparison of Percentage of Deaths Found Due to Barbiturates*

	Coroner or Medical Examiner Cases	Cases Tested for Barbiturates	Cases Tested, %	Deaths Due to Barbiturates	Deaths Due to Barbiturates, %	Yr.
San Francisco............	2,361	161	7	67	2.8	1950
Los Angeles County.....	7,539	216	3	160	2.0	1952
New York City...........	16,268	812	5	216	1.3	1950
State of Maryland.......	4,358	75	2	25	0.6	1950

Whether or not these autopsy examinations are done by qualified pathologists seems to depend on whether such men are available. Coroners, whether physicians or laymen, obviously recognize the merit of employing qualified personnel. This is evidenced by the fact that coroners' judisdictions containing over one-half of California's population (approximately 12 million) now have all coroner's medical investigations carried out by certified pathologists. The question then arises as to whether legislation might not provide certified pathologists for the more rural areas. There are approximately 125 pathologists in the state; most of these are in the metropolitan areas, and many or most of them would not be interested in medicolegal autopsy work under any circumstance. It is obvious that there would not be enough pathologists to go around and that the quantity of work in any given rural area would not justify the presence of a pathologist. Thus, in these areas, the work would still be done by whichever physician agrees to do it. As has been shown in table 1, these physicians can continue to do the work far better than has been generally recognized or admitted, provided, of course, that they do not become burdened with an endless series of trying and ultimately useless trips to the scene of many deaths. Experience shows further that by and large the men in rural areas solicit aid and advice from more experienced men when they find it necessary or advisable in doing autopsies, and assistance seems to be willingly given.

PHYSICIANS AS INVESTIGATORS

Coroners generally have a staff of lay investigators who make the "at the scene" investigation into criminal and evidential aspects of the case. These men spend all of their time at this work; most of them make a career of it. As a result, their investigations are generally very patiently and painstakingly done, certainly more so than those made by physicians most of whom consider such investigation secondary to their prime interest and training, namely, medicine. While the medical examiners require that such investigation be made by a physician, it is not clear what part of a physician's training particularly qualifies him to investigate these criminal and evidential matters.

Furthermore, with no intent to dramatize, but yet to be frank and practical, the physician must be very rare who, as a required part of the "at the scene" investigation, would routinely slip his hands into the urine-stained and feces-stained clothing of dead persons in search of identification, personal effects, notes, or other evidence. He must be rarer still who would with regularity make a detailed and exacting search of the body and the premises in which was found a reeking, vermin-infested corpse, which may or may not be liquefying. These actually are not uncommon findings. In the eyes of most physicians, whether autopsy surgeons or not, these cases are unpleasant enough at the autopsy table, and they are not eager to go to the place of death to examine and inspect before a preliminary preparation of the body has been made. It is not suggested that there are no physicians who can and will do this work. While most physicians have, on occasion, faced and coped with situations such as just described, the considerable point arises as to whether they would make this a daily routine. Physicians who would be willing would be difficult, if not impossible, to find and keep at the job.

On the other hand, there is an adequate number of lay investigators whose need and pride in the position is sufficient enough to enable them to tolerate the more unpleasant aspects, however distasteful. Such thorough and painstaking investigation as described is essential, even under the most trying circumstances, if all the information available at the scene is to be found.

Some propose that investigating the criminal and evidential aspects of any case should be a police function, since it does not fall within the province of medicine. First, the average policeman would be unwilling or incapable of bringing himself to make an adequate examination in many cases. Second, he might see only two or three coroner's cases a year and thus be wholely unqualified. If the police are to assign one or more men to make all these investigations, then it would be better for them to work under the supervision of the coroner so that their work would be properly directed. In this case, they might as well be called investigators and be in the coroner's direct employ, as they already are. Above all, if one fully understands the purpose of the coroner's office, he can see that the coroner's investigation is not, and should not be, a police function.

CORONER'S INQUEST

A study of the laws relating to the duties and powers of the coroner indicates that he must make an independent investigation into the cause and circumstances of certain deaths, order necessary medical examinations, and then conduct an inquest. At the inquest, the testimony of the various witnesses and investigators is heard along with the medical opinions or conclusions drawn by the autopsy surgeons. From this the jury decides whether there is a suspicion of a crime connected with the death. If the jury finds reasonable cause to suspect that a crime has been committed and so states in its verdict, a warrant is issued for the person charged with the crime, if he is not already in custody, and he is then brought before a judge. (It should be understood that the verdict of a coroner's jury brings charges only; it is not a conviction or in any way a proof of guilt.)

These functions seem to duplicate quite closely the activities of the police investigation, the district attorney's presentation of the evidence to the grand jury, and the grand jury's indictment that brings the accused before a judge. Since the coroner also investigates and presents the evidence to a jury and the jury orders the accused to be brought before a judge, it should be apparent that those who wrote the laws intended that a lay body, composed of coroner and jurors, carry out this combined function as a means of checks and balances for the various law enforcement agencies, at least in the matter of major crimes. The coroner and coroner's jury serve as an auditor and give assurance of an investigation and ultimate prosecution of crimes within its jurisdiction. To be sure, this is not done with the legal exactness of the aforementioned groups, and quite appropriately the verdict of a coroner's jury does not bear the weight of that of a grand jury. Nonetheless, should either the police or public prosecutor wilfully or inadvertently fail to act or, for their own reasons, should they fail to bring charges and prosecute fully, an independent body (coroner and coroner's jury) will act in their stead and bring the case before the courts. This is no reflection on these agencies but is a customary procedure at all levels of government. To do away with the inquest would be to lose the continuing audit of these most important activities. This function is too valuable and necessary to be cast aside simply because it does not fall within the province of medicine, particularly since it takes but 5 to 10% of a coroner's time and accounts for an estimated 5 to 10% of the total office expenditure. Further, equally important public services contributed by the coroner's inquest are many and will be the subject of another paper.

It is unfortunate that the medical examiners have failed to recognize the purpose and valuable contribution of the coroner's inquest. They have done away with it principally because it does not fall within the realm of medicine and partly because of lack of understanding of its function in government.

Proponents of the medical examiner system have stated that "for the cause of death to be determined by a jury is ludicrous."[1b] From such reasoning, one can presume that all jury proceedings at which medical evidence is given must be equally ludicrous. This, however, is not true. Firstly, the coroner's jury does not determine the medical cause of death. Secondly, there is no reason why a coroner's jury, just as any other jury, after hearing the autopsy surgeon's opinion on the medical causes of death and then the testimony of coroner's investigators, inspectors, police, and lay witnesses, should not thereafter be capable of deciding, let us say, whether or not the death was caused by a particular suspect or perhaps by an automobile that was or was not driven negligently. They are, for example, fully capable, after appropriate testimony, of deciding whether a death was accidental or intentional. Many of these and similar decisions are of considerable social significance and certainly of grave importance to the persons and families concerned. The belief that only a physician can make these decisions is presumptuous, fallacious, and not at all in keeping with the well-accepted concepts of our judicial system. If the jury fails to comprehend the medical findings sufficiently to arrive at a reasonable decision, this reflects the inadequacy of the physician presenting the findings or his lack of fidelity to his duty. It by no means suggests that the principles of the system are at fault.

CORONER'S JURIES

Coroner's juries are as excellent and qualified as the coroner chooses to have them. In San Francisco, for example, jurors are obtained from large and small business firms by having employers designate persons from their staff for jury duty. Since each jury is impanelled for one morning only and since any one firm is called upon but once a year, the request for a capable, thinking person as a juror is always met. The juries represent a good cross section of the public made up of intelligent and interested men capable of reasonable decisions.

The verdicts of the jury are not and need not be in any way directed by the coroner. Presenting evidence and testimony impartially can be done in such manner that a body of reasonable men can arrive at a just and proper decision. Any departure from such procedure can only be the result of a lack of interest or integrity on the part of the particular coroner. This should not be construed as a failing of the system but of the coroner himself. This lack of interest does not appear prevalent in California nor necessarily to any greater extent than would be the case if all coroners were physicians. In any event, the failings that might be found in a coroner's inquests or juries should be treated as individual problems that certainly are amenable to correction. The complete discard of the inquest, as a solution to these relatively minor problems, seems a drastic and ill-advised step. However trite it may sound, we should not be so foolish as to cut off the head to cure the headache.

It is said that, "all the problems associated with the internal administration of a medical examiner's office are a direct heritage from the coroner system."[1b] This reminds one of the rationalizing mother who believes that surely all of her child's failings and inadequacies stem from the husband's side of the family and who happily attributes all the child's favorable qualities to herself. One should remember that the only essential difference between a good coroner's office and a good medical examiner's office is that, in the latter, physicians make the "at the scene" investigations and, also, inquest hearings are not held. Otherwise, the actual conduct of the two offices is similar. It is small wonder, then, that the problems of internal administration of the two offices are alike. And, most importantly, it is apparent that the change to the medical examiner system has not solved these problems. It is enough to say that untiring efforts are needed in both offices to eliminate these problems.

CORONER'S LAWS

The laws in California are complete and adequate. A careful comparison with laws governing the various medical examiner systems reveals no significant differences. The type of case and circumstances surrounding deaths that legally require investigation are virtually identical. In California, the coroner is free to decide in which cases autopsy shall be performed. Not all medical examiners enjoy this freedom to investigate impartially and independently; some must obtain permission to proceed from other law enforcement agencies. This very important principle of independence of action should be maintained to provide a medicolegal system of force and value.

PHYSICIAN OR LAYMAN AS CORONER

The question arises whether it should be required that all coroners be physicians. It is my opinion that such a requirement would be advisable. While the many lay coroners are doing a creditable job, a large proportion of the coroner's work, in addition to being supervisory, deals with medical matters. In most jurisdictions, it is best to have a common direction of medical, technical, and investigative personnel in order to integrate their various activities. This could most easily be done by someone trained in the medical sciences. While all "at the scene" investigation need not, and perhaps should not, be made by a physician, the work of the autopsy surgeon, toxicologist, pathologist, and technician is better understood by a physician and thus better integrated into the investigation. For these reasons, the work should be overseen by a coroner who is a physician.

It is often held that a lay coroner who is a good administrator can do an adequate job if he seeks and engages competent medical guidance. This is true, but, if one can find a physician who also is a good administrator, the approach is more direct and effective and, to be sure, more economical. It is mainly for these last reasons that a physician is recommended for the position of coroner.

Juries often require guidance on medical matters. While it is safe to say that the reading of a medical report will be comprehended by the jurors if set forth by the autopsy surgeon in appropriate language, it is a considerable advantage if the report is actually presented by a physician who can answer any questions or dispel any doubts as they arise in the minds of the jurors. Many cases heard at the inquest involve the testimony of physician witnesses who may have been in attendance before the death. It is important to have the questioning

CLINICAL NOTES

THROMBOCYTOPENIA INDUCED BY SODIUM PARA-AMINOSALICYLIC ACID

REPORT OF A CASE

Harold A. Wurzel, M.D.
and
Robert L. Mayock, M.D., Philadelphia

Thrombocytopenia has followed the administration of various drugs. Para-aminosalicylic acid has not heretofore been incriminated, and, therefore, it is of interest to record thrombocytopenia following its administration.

REPORT OF A CASE

An 18-year-old Negro girl was admitted to the medical service of the Hospital of the University of Pennsylvania on Feb. 5, 1952, with the symptoms and signs of tuberculous peritonitis of about six months' duration. There was no history of abnormal bleeding, and there was no family history of hemorrhagic tendency. At laparotomy performed on Feb. 8, 1952, ascites was present and tubercule-like lesions were seen scattered throughout the abdomen. Biopsy revealed pathological evidence of tuberculosis.

Pertinent laboratory findings included: hemoglobin level, 9.8 mg. per 100 cc.; leukocytes, 5,900 per cubic millimeter; differential count, normal; prothrombin time, 64% ± 20%; serum proteins, 7 gm. per 100 cc.; albumin, 2.7 gm. per 100 cc.; and globulin, 4.3 gm. per 100 cc. The Mantoux test was positive with 0.1 mg. of old tuberculin. Urinalysis, blood serology, blood urea nitrogen, fasting blood sugar, serum bilirubin, and a chest roentgenogram showed nothing abnormal.

Administration of streptomycin, 0.5 gm. every six hours intramuscularly, was started on the day of operation. After six days, the dose was reduced to 0.5 gm. every 12 hours. Two days later, administration of sodium *p*-aminosalicylic acid (PAS), 3 gm. orally every 6 hours, and procaine penicillin, 300,000 units intramuscularly every 12 hours, was begun. The immediate postoperative course was satisfactory, and the patient was afebrile by the seventh postoperative day.

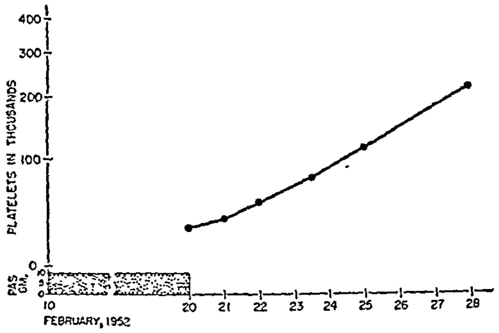

Fig. 1.—In patient with thrombocytopenia, platelet count rose after administration of streptomycin and sodium *p*-aminosalicylic acid (PAS) was discontinued.

On the tenth day after operation, the patient suddenly vomited large amounts of coffee-ground material along with blood clots. Studies of her clotting mechanism the next day gave the following values: bleeding time, 6 minutes, 30 seconds; prothrombin time, 45% ± 17%; AC globulin, 70%; prothrombin consumption, 16.6 seconds (poor utilization); Lee-White coagulation time, 19 minutes, 30 seconds; clot retraction, poor; and platelets, 30,000 and 38,000 per cubic millimeter (fig. 1). Marrow aspiration showed hypercellularity with marked increase in megakaryocytes, many of which were immature, and a normal and orderly maturation of the red and white blood cell precursors. At this time all medication was discontinued. Blood transfusions, a total of 1,500 cc., were given over the next few days with elevation of the hemoglobin level from 7.2 to 11.4 gm. per 100 cc. Gastrointestinal series showed no abnormality of the stomach or duodenum. By the 13th postoperative day, three days after discontinuance of all medication, the platelet count had risen to 76,000 per cubic millimeter. It was decided to resume the administration of streptomycin, and 0.5 gm. was given every 12 hours. No further bleeding occurred, and the platelet count continued to improve. On Feb. 27, the 17th postoperative day, the patient was discharged with instructions to receive streptomycin, 1 gm. intramuscularly twice weekly, and to continue bed rest at home.

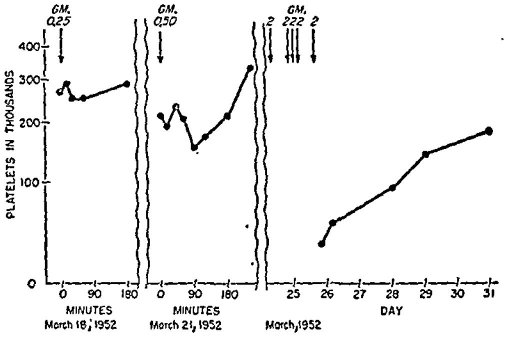

Fig. 2.—Single doses of 0.25 and 0.5 gm. of sodium *p*-aminosalicylic acid (PAS) did not cause permanent drop in number of platelets but five doses (2 gm. each) did. Platelet count rose when drug was discontinued.

Since the readministration of streptomycin failed to reproduce the thrombocytopenia, sodium *p*-aminosalicylic acid was considered the probable causative agent, and it was decided to re-call the patient for test doses of this drug. On March 18, 0.25 gm. of sodium *p*-aminosalicylic acid caused no permanent decrease in the number of platelets during a three hour period of observation. On March 21, 0.5 gm. was similarly found to have no significant effect. Reassured by these observations, it was decided to resume therapy with *p*-aminosalicylic acid. Accordingly, on March 24, a dosage of 2 gm. three times a day was instituted. On March 26, after the patient had been given a total of 10 gm. of sodium *p*-aminosalicylic acid, the platelet count had fallen to 38,000 per cubic millimeter (fig. 2). Marrow examination again revealed large numbers of megakaryocytes, many of which were immature. No abnormalities of granulopoiesis or erythropoiesis were noted. Therapy with *p*-aminosalicylic acid was again discontinued and the patient readmitted to the hospital. Five days later, the platelet count had risen to 192,000 per cubic millimeter. Menstruation, which had begun March 24, was more profuse than usual.

Since it was felt that sodium *p*-aminosalicylic acid constituted a valuable agent in the treatment of this patient, the test dose procedure was repeated during the second hospital stay. No platelet fall was noted after single doses of 1 gm. on April 1 or after 2 gm. given the following day. On April 3, a single dose of 4 gm. produced a fall in platelets from 318,000 to 60,000 per cubic millimeter (fig. 3) within 90 minutes. Administration of the drug was then permanently discontinued. The platelet count rose slowly and reached 280,000 per cubic millimeter on April 9, the day of discharge. Streptomycin, 1 gm. twice weekly intramuscularly, was continued. The patient has continued to improve, showing weight gain and absence of pain, fever, and ascites. Six platelet counts performed during the next four months were normal, and no further hematological difficulties have appeared.

This study was aided by the Elizabeth and Mario Peruzzi Fund for Pulmonary Research and the Eli Lilly Hematology Fund.

From the Hematology Section and Chest Clinic of the Department of Medicine of the Hospital of the University of Pennsylvania.

COMMENT

The causative relationship of sodium *p*-aminosalicylic acid administration to the thrombocytopenia in this patient seems well established. Although streptomycin reportedly may cause thrombocytopenia,[1] there was no evidence in this case that it did. Thrombocytopenia occurred only when sodium *p*-aminosalicylic acid was given.

In drug-induced hypersensitivity reactions, the fall in platelet count usually occurs after very small amounts of the offending agent are given. In this patient, a therapeutic dose was required to give the effect. Despite this, we believe the reaction indicated hypersensitivity rather than a toxic depression of the bone marrow. Marrow aspirations showed increased numbers of megakaryocytes of an immature type, with no evidence of marrow destruction. This marrow picture, like that in idiopathic thrombocytopenic purpura, is suggestive of a maturation arrest mechanism affecting the megakaryocytes. The sudden fall in the number of platelets occurring within 90 minutes after an effective test dose of the drug (fig. 3) is believed to imply an additional peripheral mechanism as well. The peripheral mechanism, occurring with shock-like speed, is probably one of agglutination and destruction of platelets.

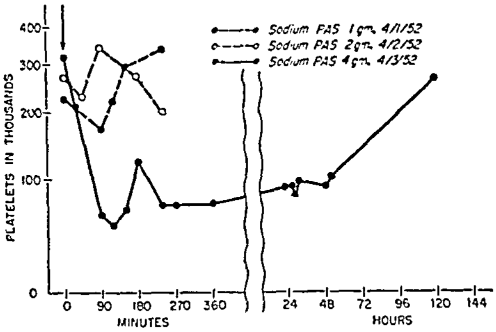

Fig. 3.—Single doses of 1 and 2 gm. of sodium *p*-aminosalicylic acid (PAS) did not cause permanent or major decrease in number of platelets, but a dose of 4 gm. caused platelet count to drop from 318,000 to 60,000 per cubic millimeter.

Nonthrombocytopenic purpura following *p*-aminosalicylic acid administration has been reported previously,[2] but this was probably anaphylactoid in nature since platelets and coagulation factors were normal in these patients. Bigelow and Desforges [3] have reported two cases of thrombocytopenic purpura associated with quinidine ingestion. In one of these cases, they were able to demonstrate a factor in the patient's platelet-poor plasma that caused agglutination of normal platelets in the presence of quinidine. They also report similar work done by Ackroyd using Sedormid ([2-isopropyl-4-pentenoyl] urea). It seems probable that a similar mechanism was operative in our patient.

Since hemoptysis is a common manifestation of pulmonary tuberculosis, it behooves the attending physician to determine whether hemoptysis or other hemorrhagic phenomena occurring in patients receiving *p*-aminosalicylic acid are the result of thrombocytopenia secondary to the drug therapy. Since streptomycin has also been found to cause thrombocytopenia,[1] differentiation may be difficult when these drugs are used in combination.

SUMMARY

Thrombocytopenia with hematemesis was observed in a patient after administration of sodium *p*-aminosalicylic acid (PAS). The causative relationship of the sodium *p*-aminosalicylic acid to the thrombocytopenia was established during two test periods. The reaction was apparently of the hypersensitive type, and it is suggested that the mechanism involved agglutination and destruction of the platelets together with maturation arrest of the megakaryocytes.

ADDENDUM

Since this paper was written, Hayes and Wise [4] have reported on a patient in whom thrombocytopenia followed the administration of *p*-aminosalicylic acid.

LIGATION OF HEPATIC ARTERY FOR PORTAL HYPERTENSION

CLINICAL APPLICATION OF EXPERIMENTAL OBSERVATIONS

H. Popper, M.D.
N. C. Jefferson, M.D.
and
H. Necheles, M.D., Chicago

Good clinical results are the decisive factor in the acceptance of a novel procedure by the medical profession. However promising results of experiments may be, it is only the clinical application that proves their practical value. Inappropriate application or undeserved criticism can discredit new ideas easily. There is a tendency to overestimate the possibilities of new procedures, to apply them too widely, and then, on the basis of unsatisfactory results, to declare them as failures and to warn against their use.

The above ideas apply to ligation of the hepatic artery for portal hypertension, a procedure for which definite indications and contraindications have not yet been established. In the following report, we want to point out experimental observations that may be of clinical value and that may explain some of the clinical failures.

The liver obtains oxygen from both arterial and venous blood, and it has been claimed [1] that more than 50% of the oxygen used by the liver is supplied by portal blood. We have demonstrated, however, that in the dog arterial blood is the main source of oxygen for the liver.[2]

Arterial blood enters the liver through its hilum in branches of the hepatic artery and its collaterals and through the coronary ligaments in the hepatic branches of the phrenic arteries. This latter source of arterial blood, which was neglected in many previous investigations, shows marked anatomic variations. We have shown [3] that survival of the liver after complete excision of the hepatic artery depends on the presence of arterial blood supply through the phrenic arteries, in addition to portal blood. Fatal liver necrosis develops regularly when ligation of the hepatic branches of the phrenic arteries is added to excision of the hepatic artery.

This shows that the liver cannot survive on portal blood alone and that it needs some arterial blood. However, it is hazardous to rely on the hepatic branches of the phrenic arteries, which vary much in number and size in dogs as well as in man, for this arterial blood supply. Attempts by the surgeon to decrease the arterial blood supply of the liver should, therefore, stop short of complete occlusion of all arterial channels that enter through the porta hepatis. After ligature of the splenic, the common hepatic, and the left gastric arteries, arterial blood can enter the liver by reverse flow through the gastroduodenal branch of the superior mesenteric artery, if the arterial distribution conforms to anatomic normality. If subtotal gastrectomy is added to such a procedure, the hepatic arterial blood supply may be interrupted completely if the pancreaticoduodenal branches are interfered with in the process of mobilizing the duodenum. Even if the anastomosis of the hepatic artery with the superior mesenteric artery is not jeopardized, there is danger. In 5 out of 11 dogs in which the common hepatic artery was ligated and transected, we found that collateral arterial circulation to the liver did develop by reversed flow through the gastroduodenal or right gastric arteries. During these operations, active arterial bleeding from the peripheral stump of the hepatic artery suggested that retrograde arterial blood flow was present and would persist. The occurrence, however, of thrombosis, vasospasm, and anatomic variations apparently makes the establishment of such circulation uncertain and hazardous. If, in addition to the splenic and the left gastric arteries, the hepatic artery is ligated distal to the gastroduodenal artery, namely between the origin of the gastroduodenal artery and the hilum of the liver, the hepatic arterial blood supply through the hilum is interrupted completely, with the possible exception of overlooked collaterals. Of course, in all these situations the hepatic branches of the phrenic arteries still function, but their efficiency seems rather unpredictable. These facts may explain some of the unfavorable results of ligation of the hepatic arterial blood supply.

Experimentally, others [4] and we ourselves [2b] have been able to demonstrate that the liver survives practically complete occlusion of its arterial and venous blood supply, if this is performed in several stages. These observations should be of clinical value. It is apparently not advisable to attempt complete interruption of the hepatic arterial circulation in one stage. Ligation of the hepatic, the splenic, and the left gastric arteries should preferably be performed in several stages. This permits a study of the reaction of the liver to a limited diminution of its arterial blood supply, and it indicates its probable reaction to complete elimination of arterial circulation before it is too late. The liver also has time to become adjusted to a lower supply of oxygen, and it will survive even if no reverse flow occurs and even if the supply through the hepatic branches of the phrenic arteries happens to be completely insufficient.

Ligation of the hepatic artery lowers portal hypertension of Laennec's cirrhosis,[4] supposedly because intrahepatic arterioportal anastomoses increase portal pressure and interfere with portal blood flow.[5] This rationale of hepatic artery ligation points already to certain limitations. Wherever portal hypertension is not due to interference of the arterial circulation with the portal circulation, no beneficial effect can be expected from ligation of the hepatic artery.

Furthermore, we have demonstrated that ligation of the hepatic arterial blood supply is almost regularly fatal in the presence of impaired portal circulation that is produced by marked constriction of the portal vein.[2b] A similar condition must exist in patients with impaired portal circulation when the hepatic artery is ligated; therefore, only if it is certain that the portal circulation will be improved by ligation of the hepatic arterial blood supply, should such procedure be performed. If the portal circulation is not improved by ligation of the artery, we will deprive a liver with already impaired portal circulation, which is more dependent on its arterial blood than a normal liver, of part of its essential blood supply. It seems, therefore, urgent that systematic investigations be done to establish the type of portal obstruction, in addition to Laennec's cirrhosis, in which a beneficial effect on portal pressure and portal circulation is to be expected after ligation of the hepatic artery.

SUMMARY AND CONCLUSIONS

Under normal conditions, the liver obtains oxygen through the hepatic artery, the hepatic branches of the phrenic arteries, and the portal vein. Animal experiments show that, in addition to the portal blood, a definite minimal amount of arterial blood is necessary for survival of the liver. After ligation of the common hepatic, the splenic, and the left gastric arteries, the liver receives arterial blood through only the hepatic branches of the phrenic arteries and, by reverse flow, the gastroduodenal artery. The development of reversed circulation through the gastroduodenal artery is uncertain and unpredictable.

Combining the above procedure with gastrectomy jeopardizes the development of reversed flow in the gastroduodenal artery, and hepatic branches of the phrenic arteries are possibly the only source of arterial blood

supply. Ligation of the splenic, the left gastric, and the hepatic arteries, the latter distal to the origin of the gastroduodenal artery, limits the supply of arterial blood to the liver to the phrenic arteries. Unfavorable results following these procedures may be due to inadequate development of the hepatic branches of the phrenic arteries and to variations in vascular anatomy and function of the hepatic artery and its branches.

Animal experiments show that the liver can be deprived almost completely of its blood supply if this is done in stages. This is not due to revascularization of the liver by collateral circulation but to the fact that the liver can adjust gradually to a drastically lowered blood suppy. Ligation of the hepatic arterial blood supply and its collaterals should possibly be done in stages. Systematic investigations should be undertaken to establish the types of intrahepatic portal obstruction, in addition to Laennec's cirrhosis, in which ligation of the hepatic artery will cause lowering of portal hypertension.

BLEEDING ESOPHAGEAL VARICES WITHOUT OTHER SIGNS OF HYPERTENSION IN A CHILD

James Mithoefer, M.D., Cooperstown, N. Y.

There are instances in which a careful investigation fails to reveal the source of massive gastrointestinal hemorrhage. When there are secondary evidences of portal hypertension, one concludes that bleeding varices of the esophagus are the cause. The case presented here illustrates that varices of the esophageal veins may be present and may be the source of fatal hemorrhage in childhood without other signs of portal hypertension.

REPORT OF A CASE

This child was 2½ years old at the time of her first admission to the Children's Hospital, Cincinnati, on April 6, 1950, because of massive gastrointestinal hemorrhage. She had been born at term after an uncomplicated pregnancy, and her growth and development had been normal until diarrhea developed 10 months before this admission. After the child had had several watery stools a day for two weeks, her parents noticed that her stools became black and foul smelling and that she seemed pale and listless and sweated unduly. She was admitted to a hospital in another city where she received two blood transfusions and was discharged after a stay of three days. She apparently regained her normal health until three weeks later when tarry stools were again noticed as were pallor, weakness, and sweating. She was readmitted to the other hospital, more blood transfusions were given, and laparotomy was performed. The surgeon was unable to locate a source of bleeding. Shortly after her recovery from the operation, she was taken to a midwestern clinic where an extensive investigation failed to reveal a source of gastrointestinal bleeding. It is significant that there was no sign of bleeding during her stay at the clinic, that the liver was palpable 2 fingerbreadths below the right costal margin, and that the spleen was not palpable. It is also of interest that the roentgenologic examination of the gastrointestinal tract was reported as normal, but no specific mention was made of the esophagus.

The child was then entirely well until March, 1950, when chickenpox developed. Two days after the appearance of the exanthem, she began to pass black stools that became red and contained blood clots. She was admitted to another hospital where three transfusions were given, but further diagnostic studies were not carried out. On April 6, 1950, she complained that her stomach hurt and began to pass grossly bloody stools. After passing eight or nine such stools, she was brought to the Children's Hospital. While en route she vomited red blood. This was the first time hematemesis occurred.

Her family history and her history were irrelevant and noncontributory. Examination showed her to be an alert, cooperative child who did not appear chronically ill. Her weight was 26 lb. 4 oz. (10.5 kg.) and her height 33½ in. (85.09 cm.). Her pulse rate was 180 per minute, respiratory rate 28 per minute, and blood pressure 115/45 mm. Hg. There was no icterus. The skin showed no telangiectases, petechiae, or purpuric areas. Her head, including the mouth and pharynx, and her heart, lungs, and extremities were not significantly abnormal. The abdomen was soft, slightly convex, but not distended. There was a healed right rectus surgical scar. The smooth, nontender liver edge was at the level of the costal margins. The spleen was not palpable. Rectal examination revealed no abnormality within or outside the lumen.

Examination of the blood showed it contained 5 gm. of hemoglobin per 100 cc. and 1,710,000 erythrocytes per cubic millimeter, with 1.9% reticulocytes. There were 10,300 white blood cells per cubic millimeter, with a normal differential count and 340,000 platelets per cubic millimeter. Except for the presence of acetone, urinalysis was normal. The serum contained 32 mg. of nonprotein nitrogen per 100 cc.; its pH was 7.47; and it contained 23.8 mM. of carbon dioxide per liter; 108 mEq. of chloride per liter, 3.5 gm. of albumin per 100 cc., and 1.5 gm. of globulin per 100 cc. The prothrombin time was 23.4 seconds. The capillary bleeding time was 4 minutes and the clotting time 10 minutes as determined by the Lee-White two tube method. The tourniquet test showed four petechiae per square inch after five minutes.

Roentgenologic examination of the gastrointestinal tract after a barium meal showed that the wall of the esophagus was smooth, without evidence of varices. The stomach contained multiple filling defects that were thought to be blood clots, but one in the region of the duodenum had the appearance of a polyp on a long pedicle. There was no spasm or other evidence of ulcer in the stomach or duodenum. The passage of barium through the small bowel and colon was normal.

The investigation described above was carried out in the first 48 hours of the patient's hospital stay. During that time, vigorous rectal bleeding continued so that, after receiving a total of 1,050 cc. of blood intravenously, the child's hemoglobin level was still only 12 gm. per 100 cc. On the assumption that the filling defect in the region of the duodenum might be a polyp, it was decided to perform laparotomy; therefore, another 700 cc. of blood was given. At 2 a. m. on April 9, 1950, laparotomy was performed through a long right rectus incision. The entire gastrointestinal tract from the cardia of the stomach to the rectum was inspected and palpated, but no evidence of bleeding was found. The stomach was opened at the pylorus, and its interior and the interior of the first portion of the duodenum were palpated and inspected. The lower 7 cm. of the esophagus and of the remainder of the duodenum to the ligament of Treitz were normal to palpation. The liver and spleen were of normal size and consistency. No dilated veins of the portal system were seen; there was no excessive vascularity of the gastrosplenic or lienocolic ligaments. The extrahepatic biliary tract appeared and felt normal. The splenic vessels and the portal vein were not exposed, but the upper border of the pancreas and the hilum of the liver felt normal.

There were no more episodes of bleeding after operation, and the girl was sent home on April 26, 1950. She remained well and active until June 9, 1950, when measles developed and a large tarry stool was passed. She was taken to the contagious division of the Cincinnati General Hospital where, shortly after admission, she had a massive hematemesis and died.

From the Mary Imogene Bassett Hospital, Cooperstown, N. Y., and the Department of Surgery, College of Physicians and Surgeons, Columbia University, New York.

At autopsy, the esophagus was opened in situ. Its wall was of average thickness, and it was lined by longitudinally folded, whitish, glistening mucosa. The mucosa of the distal two-thirds of the esophagus contained three prominent, dilated, longitudinal tortuous veins. Along the course of one of these veins about 2 cm. from the cardia, there was a red plug of clotted blood in a perforation of the vein. Immediately above the cardia there were several puckered white scars overlying dilated veins. The liver weighed 390 gm. and the spleen 60 gm. The liver was of normal consistency and friability. The capsule of the spleen was slightly thickened and mottled with dark brown confluent foci of discoloration; its cut surface showed a pinkish, meaty parenchyma with accentuated trabecular markings. Less than the usual amount of pulp was obtained on scraping the surface. The parenchyma was mottled with confluent ovoid, dark brown, hemorrhagic foci. The splenic vein, as well as the portal vein and its other tributaries, was patent. Histological examination of the liver showed no abnormality. The spleen showed evidence of mild splenitis and recent passive congestion consistent with the presence of measles. The remainder of the examination revealed no significant abnormality.

COMMENT

Bleeding from esophageal varices is uncommon in children. In the records of the Columbia-Presbyterian Medical Center in New York between 1932 and 1952, there are 501 cases of which 36 were in children under the age of 14. The reports on the subject deal principally with patients who had other obvious manifestations of portal hypertension.[1] Review of 29 of the 36 cases from the Columbia-Presbyterian Medical Center shows that in each instance other evidences of portal hypertension were present. Whipple,[2] Rousselot,[3] Thompson,[4] and others have described the mechanism of formation of varices of the esophageal veins in cases in which obstruction near the termination of the portal system produces increased portal pressure.

There are a few reports of esophageal bleeding without portal hypertension in the literature. Friedman[5] has reported the case of a 3½-year-old boy who died after several massive gastrointestinal hemorrhages. Autopsy showed large varices in the esophagus and a grossly normal liver and spleen, although the latter had previously been enlarged on physical examination. The viscera were not examined microscopically. Nochimowski[6] reported two instances of death from bleeding esophageal varices in adults. In each case, the liver was reported to be quite healthy, and no cause of the varices could be found. Both of these authors expressed the opinion that varices of the esophageal veins are caused by a congenital defect. In support of this opinion, Nochimowski points out that varices do not develop in all persons with Laennec's cirrhosis and portal hypertension. He postulates that an underlying deficiency in the vein must be present before it will give way to increased intraluminal pressure. Further supporting evidence has been offered by Weinberg[7] who reviewed 1,189 consecutive autopsies in which 95 instances of esophageal varices were demonstrated; in only 23% was there associated liver disease. Furthermore, of 30 cases of Laennec's cirrhosis, varices were demonstrable in only 43%. Severe disease of the cardiorespiratory system was present in an additional 56 cases. In view of these data, Weinberg concluded that congenitally weak spots may exist in the esophageal veins and that, under the influence of portal hypertension, hypoxia, or other adverse conditions, such areas may dilate.

Those who have dealt surgically with portal hypertension recognize that secondary evidence of increased vascularity of the portal system may not be grossly apparent and that the only reliable test for its presence is direct measurement of pressure in the portal system. This measurement was not made in the case under discussion; therefore, it can not be said that the portal pressure was normal. The most that can be said is that no cause for portal hypertension was found and that esophageal varices constituted the only indirect sign of portal hypertension after death.

The correct diagnosis in the case described was not made because signs of portal hypertension were not present at operation, and because varices were not demonstrated by roentgenologic examination. Measurement of the portal pressure at the time of laparotomy might have been of help, although it must be realized that, in the presence of diminished effective blood volume, an elevated portal pressure may fall to normal or below. More attention should have been paid to the esophagus during roentgenologic examination, perhaps with the roentgenogram being made while the patient performed the Valsalva maneuver. Had there been any indication of the presence of varices, esophagoscopy should have been performed. Had the diagnosis been established, proper therapy could have been instituted. If the portal pressure had been found to be elevated, splenectomy and splenorenal shunt would have been performed. If no portal hypertension had existed, it would have been logical to resect the lower portion of the esophagus and perform esophagogastrostomy.

SUMMARY AND CONCLUSIONS

A case of fatal hemorrhage from varices of the esophageal veins without evidence of portal hypertension in a child is presented. The importance of considering varices of the esophagus as a cause of unexplained gastrointestinal bleeding is emphasized, since special diagnostic aids may be necessary to establish a diagnosis.

COUNCIL ON FOODS AND NUTRITION

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

Beech-Nut Packing Company, Canajoharie, New York.

Beech-Nut Junior Sweet Potatoes.

Ingredients: Sweet potatoes, salt, and water sufficient for preparation.

Analysis (submitted by manufacturer).—Total solids 20.56%, moisture 79.44%, ash 0.99%, fat (ether extract) 0.41%, protein (N × 6.25) 0.87%, crude fiber 0.64%, carbohydrate other than crude fiber (by difference) 17.65%.

Vitamins and Minerals	Per 100 Gm.
Thiamine	26 mcg.
Riboflavin	20 mcg.
Niacin	0.42 mg.
Ascorbic Acid	14.4 mg.
Crude Carotene	4.4 mg.
Vitamin A Equivalent	7333 I. U.
Calcium	21 mg.
Phosphorus	35 mg.
Iron (total)	0.50 mg.
Iron (available)	0.48 mg.
Copper	0.17 mg.

Calories.—0.82 per gram; 23.2 per ounce.

Use.—For use in the feeding of older infants and young children.

Swift and Company, Chicago.

Swift's Strained Egg Yolks for Babies.

Ingredients: Raw egg yolks, water, and salt.

Analysis (submitted by manufacturer).—Total solids 30.8%, moisture 69.2%, ash 1.4%, fat 18.7%, protein 10.4%, carbohydrate 0.3%, and salt 0.65%.

Vitamins and Minerals	Per 100 Gm.
Vitamin A	1,200 I. U.
Vitamin D	210 I. U.
Thiamine	0.06 mg.
Riboflavin	0.2 mg.
Niacin	0.1 mg.
Calcium	70 mg.
Phosphorus	270 mg.
Iron	2.6 mg.

Calories.—2.11 per gram; 59.8 per ounce.

Use.—For use in the feeding of infants and young children and in special diets.

Comstock Canning Corporation, Newark, N. Y.

Comstock Brand Dietetic Pack Diced Carrots.

This product consists of Red Cored Chantenay carrots packed in water without any added salt.

Analysis (submitted by manufacturer).—Total solids 7.03%, moisture 92.97%, fat extract 0.14%, protein 0.4%, crude fiber 0.6%, available carbohydrate 5.30%, sodium 14.4 mg./100 gm.

Calories.—0.27 per gram; 7.7 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Comstock Brand Dietetic Pack Cut Green Beans.

This product consists of Tendergreen variety beans packed in water without any added salt.

Analysis (submitted by manufacturer).—Total solids 4.43%, moisture 95.57%, fat extract 0.06%, protein 1.1%, crude fiber 0.7%, available carbohydrate 2.25%, sodium 0.3 mg./100 gm.

Calories.—0.17 per gram; 4.8 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Comstock Brand Dietetic Pack Whole Kernel Golden Sweet Corn.

This product consists of Tendermost variety sweet corn packed in water without any added salt.

Analysis (submitted by manufacturer).—Total solids 16.53%, moisture 83.47%, fat extract 0.28%, protein 2.5%, crude fiber 0.8%, available carbohydrate 12.6%, sodium 3.6 mg./100 gm.

Calories.—0.53 per gram; 15.0 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

Gerber Products Company, Fremont, Mich.

Gerber's Junior Prunes.

Ingredients: Prunes with enough water added to prepare properly.

Analysis (submitted by manufacturer).—Total solids 25.94%; moisture 74.06%, ash 0.91%, fat (ether extract) 0.22%, protein (N × 6.25) 0.80%, crude fiber 0.89%, carbohydrates other than crude fiber (by difference) 23.12%.

Vitamins and Minerals	*Per 100 Gm.*
Vitamin A (carotene)	692.0 U. S. P. units
Thiamine	0.017 mg.
Riboflavin	0.129 mg.
Ascorbic Acid	4.935 mg.
Niacin	0.603 mg.
Calcium	27.3 mg.
Phosphorus	24.0 mg.
Iron	1.26 mg.

Calories.—0.97 per gram; 27.61 per ounce.

Use.—For use in the feeding of older infants and young children.

S. S. Pierce Company, Boston.

Overland Brand Dietetic Pack Peas and Carrots.

This product consists of the vegetables packed in water without any added salt.

Analysis (submitted by distributor).—Total solids 8.3%, moisture 91.7%, fat extract 0.16%, protein (N × 6.25) 1.95%, crude fiber 0.99%, available carbohydrates 3.88%, sodium 14.90 mg./100 gm.

Calories.—0.25 per gram; 7.1 per ounce.

Use.—For use in low-sodium and other therapeutic diets.

H. J. Heinz Company, Pittsburgh.

Heinz Strained Cream of Tuna.

Ingredients: Tuna fish (fillet), carrots, wheat flour, corn starch, cream, whole milk powder, onions, salt, and water.

Analysis (submitted by manufacturer).—Total solids 16.50%, moisture 83.50%, ash 0.81%, fat (acid hydrolysis) 2.44%, protein (N × 6.25) 3.69%, crude fiber 0.39%, total sugar as sucrose 1.07%, natural reducing sugar 0.79%, acidity (as acetic) 0.09%, starch 8.06%, and salt 0.48%.

Vitamins and Minerals	Per 100 Gm.
Vitamin A activity	490 I. U.
Thiamine	9.3 mcg.
Riboflavin	33.0 mcg.
Niacin	1.23 mg.
Calcium	40.0 mg.
Phosphorus	54.0 mg.
Iron	0.10 mg.
Copper	0.11 mg.

Calories.—0.73 per gram; 20.7 per ounce.

Use.—For use as a transition food for infants from milk to semiliquid foods.

CORONER VERSUS MEDICAL EXAMINER

Elsewhere in this issue, Dr. Turkel, coroner of the city and county of San Francisco, has drawn certain interesting conclusions from a comparison of the statistical reports of the coroner's offices of several counties of California with those of the medical examiner's offices of several cities and states elsewhere in the United States. For several reasons he concludes that the work done in the coroner's office studied "surpasses in quality and amount that done in any other type of system on which statistics were available." One reason for this conclusion is that a higher percentage of autopsies was performed by the coroners than by the medical examiners. Another is that more specimens were referred for special laboratory examinations by the coroners than by the medical examiners. Still another is that as a result of such tests the coroners of San Francisco and Los Angeles discovered a higher incidence of death from barbiturate poisoning than did the medical examiners of New York City or the state of Maryland. It is gratifying to hear that, despite the handicap of laws that fail to require the coroner to be a physician and that do require that he must run for office on a party ticket if he wishes to be reelected, the offices in Los Angeles and San Francisco function as well as they apparently do according to the statistics compiled by Dr. Turkel.

It should be obvious that the name under which the medical investigation operates, whether it be coroner or medical examiner, has nothing to do with the effectiveness with which his official duties are discharged. In 1942 the committee of the American Medical Association to study the relationship of medicine and law reported that the foremost requirement for the continued existence of a competent coroner's or medical examiner's office is a law that requires first that the office holder be professionally competent and second that he have both the authority and the facilities for the conduct of such investigations as are required in the interests of public welfare. Although the selection of coroners under some form of the merit system would appear to give greater assurance of professional competence than their election by popular vote, it should not be assumed that either all appointed medical examiners are good or all elected coroners are bad.

In extolling the advantages of the coroner's office, Dr. Turkel points to the fact that the medical examiner does not have the authority to hold an inquest. Certainly inquests need to be, and are, held in certain categories of violent or unexplained deaths under both the coroner and the medical examiner systems. The coroner ordinarily initiates and presides over the inquest. Under the medical examiner system the medical examiner ordinarily requests a legally competent magistrate to hold an inquest and appears before the magistrate with whatever evidence he may have. If the coroner were a lawyer his competence to serve as a magistrate might be assumed. If he is a physician, as he should be, he probably serves the needs of justice better as witness than as a presiding magistrate.

Dr. Turkel's study is to be commended in that it indicates that much can be done to improve the operation of the office of county coroner short of replacing it by a state medical examiner system. The important thing is to move in the direction of improvement. Although Dr. Turkel has not submitted convincing evidence that it is better to keep the office in county politics than to put it under the merit system, he has shown that it is possible to do good work under great handicaps.

MEDICAL COLOR TELEVISION—STORY OF PROGRESS

The Seventh Clinical Meeting of the American Medical Association, in St. Louis, will witness a milestone in the history of medical color television when the color television unit of Smith, Kline & French Laboratories presents its 50th program of colorcasting for the medical profession. Those familiar with the history of medical color television will remember that it was at the 1949 meeting of the A.M.A. in Atlantic City where this firm's TV unit presented the first program of operations and clinics to be televised in color. Since then it has carried its services to 15 states, Canada, and France. Many "firsts" were recorded along the way. In 1951, the Canadian Medical Association was host at the first program of color television seen in Canada. From here, the unit went abroad to give Europe its first look at color TV in a program presented at the International Society of Surgeons meeting in Paris. In the first transcontinental color transmission, a coarctation was televised at the Los Angeles County Hospital and received in Chicago and New York.

Innovations in production and equipment have been introduced at almost every meeting, though many of these refinements are not obvious to the program viewers. The annual meeting of the A.M.A. in New York last summer saw the unveiling of what might be considered—from the viewpoint of the audience—the most striking additions to SKF equipment in years. The telecasts there were received on two 4½ by 6 foot screens, specially built by the Columbia Broadcasting System. These huge screens provide a picture 27 times larger than that seen on the 12-inch receivers used previously, rendering an image of great clarity. When the camera is focused on a surgical field, the view obtained by physicians in the audience is often better than that available to some members of the operating team. The dramatic character that the screens lend to surgical procedures was pointed up at a recent medical meeting when a mitral commissurotomy was being televised. The exposed heart filled almost the entire screen, and it was noticed that some persons in the audience were unconsciously moving their heads in time with the heartbeats. Another important addition to the equipment was the acquisition of a studio camera in 1951. Originally, the telecasting was done with but one surgical camera, employed for clinical presentations as well as operations. The physician conducting a clinical discussion was forced to adapt his presentation to the narrow confines of a camera designed primarily for use in an operating room. With the addition of the versatile studio camera, the variety of material used in clinical presentations has been greatly increased.

The production end of the telecasts has also undergone considerable change and improvement. Much of the responsibility for this progress can be attributed to the physicians participating in the programs. Whenever possible, they have utilized visual material in the preparation of their clinics. Through the development of production techniques, several very effective methods of presenting operations are now available to the surgeon. He can do a straight running narration as he operates, carry on a question and answer session with a member of his operating team, hold a round-table discussion with other surgeons watching the operation on a monitor located in the studio, or periodically switch to an assistant in the studio who can discuss and demonstrate clinical material pertinent to the operation.

Perhaps the greatest change of all is to be found in the motives of the persons attending the program—the audience itself. For the first few years after the initiation of color television, almost every medical meeting the SKF unit visited was seeing color television for the first time. Naturally, the sheer novelty of the medium was a strong factor in inducing the doctors to attend the telecasts. It was difficult to ascertain whether the intended purpose of the medium—that of supplementing the postgraduate teaching programs of the meetings—was successful. As it developed, the audiences did not get smaller when the element of novelty faded; rather they increased in size. This was gratifying testimony to the place medical color television had won in the estimation of physicians no longer impressed with its "newness."

One might ask just what advantages color television brings to medical meetings. Without going into detail, a few of color TV's contributions to medical education can be cited. Only through the eye of the camera can hundreds of persons be brought to within a few feet—or a few inches—of interesting visual material. In a matter of seconds, the camera can accommodate itself to objects as different in size as a minute lesion and an iron lung. On the lecture platform, it is often inconvenient for speakers to introduce patients or even other specialists into their presentations. With the TV camera, such introductions are easily handled; in fact, they are highly desirable. The doctor-participant can also illustrate graphically the points he wishes emphasized. This visual reinforcement gives presentations much more impact than mere verbal references to points. Television can shift scenes readily. Thus an orthopedist can be televised giving a clinical demonstration of osteogenic sarcoma and, a few minutes later, the same surgeon can be shown performing a resection and bone graft to alleviate this condition in a patient. Unlike films, the presentations are individualized and completely natural. Because they are unrehearsed, the programs in general and the operations in particular are subject to all the drama of the unexpected. If a surgeon encounters unforeseen difficulties, the picture is not blacked out and the hundreds of persons in the audience are given the privilege of watching a surgeon cope with an immediate problem. Finally, there is color. The sharp contrast between color and black-and-white in the demonstration of medical subject matter will be seen by physicians attending the St. Louis meeting. The engineers will, from time to time, switch the camera to black-and-white. The loss of definition, depth, and detail will be obvious, as will be the change in the richness of the picture. The all-important asset of color, in combination with the advantages already mentioned, gives color television its surpassing distinction as an instrument for medical teaching.

SANITATION OF CRUSHED ICE

One of the most interesting problems that have recently demanded attention is that of the sanitary quality of the crushed ice used for ice water and other iced drinks. Because water-borne diseases may easily be spread by contaminated ice, ice used in iced drinks or in direct contact with food should conform bacteriologically to the accepted standards for potable water. Recent investigation [1] has shown that crushed ice for these purposes is often heavily contaminated with coliform organisms. These organisms may be introduced into crushed ice in many ways, chief among which are the introduction of dust during freezing into the cake from which the crushed ice is made; contamination of the cake from the floors of freezing rooms, trucks, and restaurants; and contamination from chippers, crushed ice containers, or human hands during dispensing. Of these, handling during dispensing was found to be the most prolific source. In an effort to correct this situation, a university dining hall was selected for an experiment. A solution of sodium hypochlorite containing 2 ppm of available chlorine was added to the container of crushed ice so as to nearly cover the ice. As a result, the bacterial count was greatly reduced, and no coliform organisms were found in any of the samples taken. The best feature of this procedure was that no chlorine flavor was imparted to the ice water or iced drinks. This comparatively simple measure was so successful that it might well become standard practice in places where crushed ice is used in serving food or drinks.

MEDICAL NEWS

CALIFORNIA

Dr. Robson Named Acting Assistant Dean.—Dr. George B. Robson, associate clinical professor of medicine, Stanford University School of Medicine, San Francisco, has been named acting assistant dean of the school, succeeding Dr. William H. Northway, head of the division of physical medicine. Dr. Robson, who will remain in private medical practice in addition to his new duties as acting assistant dean, joined the medical faculty in 1937.

Annual Conference on Ophthalmology.—Stanford University School of Medicine, San Francisco, will present the annual postgraduate conference on ophthalmology, March 22-26, 1954. Registration (limited to 30) will be open to physicians who restrict their practice to the treatment of diseases of the eye or eye, ear, nose, and throat. Instructors will be Drs. A. Edward Maumenee, Dohrmann K. Pischel, Jerome W. Bettman, Max Fine, Earle H. McBain, and Arthur J. Jampolsky. Further information may be obtained from the Office of the Dean, Stanford University School of Medicine, 2398 Sacramento St., San Francisco 15.

CONNECTICUT

Meeting of Medicolegal Committee.—The first meeting of the recently formed conference committee of the Connecticut State Medical Society and the State Bar Association of Connecticut, Nov. 5, at the New Haven Lawn Club, was addressed by J. W. Holloway Jr., LL.B., Director of the A. M. A. Bureau of Legal Medicine and Legislation, who discussed the advantages and objectives of the conference type of committee organization.

Society News.—Dr. Thomas J. Danaher, Torrington, has been named chairman of the council of the Connecticut State Medical Society to succeed the late Dr. Joseph H. Howard, Bridgeport. Dr. Danaher, who is chairman of the professional policy committee and a director of Connecticut Medical Service, is also a past president of the society and of the Litchfield County Medical Association. He is attending surgeon at the Charlotte Hungerford Hospital, Torrington, a delegate from the state medical society to the American Medical Association, a director and past president of the Torrington Community Chest, and a director of the Torrington YMCA and the Diocesan Bureau of Social Service.

DISTRICT OF COLUMBIA

The Fourth Muscular Dystrophy Clinic.—The first muscular dystrophy clinic in Washington, D. C., the fourth in the United States, opened recently at Georgetown University Hospital. Dr. Tiffany Lawyer, assistant professor of neurology, is director of the clinic for the development of research in this field. Mr. Richard Woods, president, Washington chapter of the Muscular Dystrophy Association, formally opened the clinic and presented Sister Mary Antonella with a check to cover the expenditures for the first six months.

University News.—Dr. Hugh H. Hussey has been appointed head of the department of preventive medicine and public health at his alma mater, Georgetown University School of Medicine, Washington, D. C. He also becomes a member of the executive faculty of the medical school. Dr. Hussey, who interned in Georgetown University Hospital and served a fellowship in internal medicine there, was named instructor in clinical medicine at Georgetown in 1936, and in 1941 was raised to assistant professor. He is the senior consultant in medicine to Mount Alto Hospital, consultant in medicine at Glenn Dale Sanatorium, and vice-chairman of the Health Council for the Commissioners of the District of Columbia.

FLORIDA

Personal.—Dr. Fred H. Albee Jr., Orlando, has accepted an Annie C. Kane fellowship in orthopedic surgery at the New York Orthopaedic Dispensary and Hospital, Columbia-Presbyterian Medical Center. Dr. Albee will be away from his practice for one year.

Seminar in Cytodiagnosis.—A seminar will be conducted by Dr. J. Ernest Ayre, director of the Cancer Institute at Miami, Nov. 27, for physicians interested in a short course of instruction in modern techniques, methods, and procedures in the application of cytodiagnosis to cancer detection. Registration fee is $5.

Semiannual Cerebral Palsy Clinic.—Dr. Harriet E. Gillette, Atlanta, will conduct the semiannual cerebral palsy diagnostic and recommendation clinic at the Crippled Children's Society, Nov. 23-25 from 9 a. m. to 5 p. m. Dade County Medical Association members are invited to refer patients to this clinic and are asked to make their appointments through the society as soon as possible. Clinics are held under the auspices of the Florida Crippled Children's Commission.

Society News.—At its annual meeting the Heart Association of Greater Miami installed Dr. Milton S. Saslaw, Miami Beach, as president and named Dr. Morton M. Halpern, Miami, president-elect, Dr. Jack L. Wright, Miami, vice-president, and Dr. Maurice Rich, Miami Beach, secretary. Three grants for heart research and one grant toward the support of a medical social service worker at the National Children's Cardiac Home in Miami, totaling $11,372, were awarded.

GEORGIA

Fifty Year Awards.—The Medical Association of Georgia recently presented to Drs. Lloyd E. Wilson, Bowdon, and John E. Garner Sr., Thomaston, pins and certificates of distinction in recognition of 50 years of service.

Rabies in Man.—According to the U. S. Public Health Service Department of Health, Education, and Welfare, Leland E. Starr, D.V.M., Georgia Department of Public Health, has reported a case of rabies in an 11-year-old boy. About two or three weeks after being attacked by a wild fox, a pup had inflicted a mild abrasion on the boy's hand. The boy died on Sept. 8 with typical symptoms of rabies. His brain was not examined for the disease, nor were those of the dog or the fox. The history and symptoms of both animals were typical of rabies.

ILLINOIS

University News.—Northwestern University Medical School, Chicago, has named the following faculty members to hold the Wallace C. and Clara A. Abbott professorships for the academic year 1953-1954: Dr. Carl A. Dragstedt, Park Ridge, professor of pharmacology; Dr. Fred S. Grodins and Allen Lein, Ph.D., Evanston, professor of physiology and associate professor of physiology, respectively; Dr. Willard T. Hill, Highland Park, associate professor of pathology; and Dr. E. Albert Zeller, Wilmette, professor of biochemistry.——Dr. Richard E. Marcus, Winnetka, assistant professor of otolaryngology, University of Illinois College of Medicine, Chicago, has been made an associate professor at the university, where he is also director of the unit for speech and hearing rehabilitation. Dr. Jerome T. Paul, assistant professor of medicine at the university, has been promoted to associate professor.——Dr. Donald P. Morris, formerly professor of psychiatry,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Southwestern Medical School of the University of Texas, Dallas, has been appointed professor of psychiatry and mental health in the Student Health Service at the University of Illinois, Champaign-Urbana.

Chicago

Physicians' Philharmonic Society.—The embryonic Physicians' Philharmonic Society of Chicago recently met in the rehearsal hall of the Gamble Hinged Music Company, 312 S. Wabash Ave., for the first of a series of practice sessions. Among the physicians who have expressed interest in forming a permanent group are Drs. Emerson K. McVey, Henrietta M. Herbolsheimer, Will F. Lyon, Joseph G. Kepecs, Elisabeth Rybar, Anna E. Robinson, and Jacob W. Fischer, chairman. The members voted to enlarge the scope of the orchestra by inviting all members of the healing professions to join them.

Tribute to Rudolph Holmes.—The meeting of the Chicago Gynecological Society at the Knickerbocker Hotel, Nov. 20, opened with a tribute to the late Dr. Rudolph W. Holmes, by invitation delivered by Dr. Ralph E. Campbell, University of Wisconsin Medical School, Madison. Other presentations, all by invitation, were: "Follow-up on Pyelitis in Childhood, with Reference to Urinary Tract Disease During Pregnancy," by Dr. J. Donald Woodruff, Johns Hopkins University School of Medicine, Baltimore; "Circulatory Abnormalities in Pregnancy and Nonpregnancy States," by Dr. Edward A. Banner, Mayo Clinic, Rochester, Minn.; and "Nutritional Deficiencies as Casual Factors in Maternal and Fetal Mortality," by Dr. Robert McNair Mitchell, University of Pennsylvania School of Medicine, Philadelphia. An all-day clinical meeting including operative clinics and an obstetrical symposium was held at Passavant Memorial Hospital.

Personal.—Dr. John B. Hall Jr., director of the Cook County Department of Public Health, has been appointed clinical assistant professor of pediatrics at the University of Illinois College of Medicine.——Bankers Life and Casualty Company of Chicago has appointed Dr. Marvin C. Ziporyn, formerly assistant medical director of the Armour Laboratories, as medical director.——Dr. Paul R. Hawley, Chicago, director of the American College of Surgeons, was recently appointed by Governor Stratton as a member of the Illinois Board of Public Welfare Commissioners.——Dr. William S. Kroger, assistant professor of gynecology, Chicago Medical School, recently gave a lecture, entitled "Psychosomatic Aspects of Obstetrics and Gynecology," at Yale University School of Medicine, New Haven, Conn., Jewish Sanitarium and Hospital for Chronic Diseases, Brooklyn, Lenox Hill Hospital, American Society for Research in Experimental and Clinical Hypnosis, Payne Whitney Clinic, New York Hospital, Lying-In Hospital, Mount Sinai Hospital, and Sloane Hospital for Women, Columbia Medical Center, New York.——Dr. James A. Campbell, director of the medical service at Presbyterian Hospital in Chicago, has rejoined the faculty of the University of Illinois College of Medicine with the rank of professor of medicine. Dr. Campbell returned to Chicago from Albany, N. Y., where he served for two years as dean and professor of medicine at Albany Medical College.——Dr. Leonard Cardon, associate professor of medicine, Northwestern University Medical School, addressed the meeting of the 11th councilor medical district of Indiana, at Huntington, Sept. 16 on some practical considerations in the diagnosis and management of acute coronary occlusion.——Dr. Franklin C. McLean was one of 11 faculty members of the University of Chicago retired with an emeritus status at the close of the recent summer quarter. Dr. McLean will remain at the university to continue research on the physiology of bone, a project now being conducted on a Josiah Macy Jr. Foundation grant.

MINNESOTA

New Occupational Medicine Academy.—On Oct. 1 the Minnesota Academy of Occupational Medicine and Surgery was organized in Minneapolis, and the following officers were elected: president, Dr. Wilford E. Park; vice-president, Dr. John F. Shronts; secretary, Dr. Leslie W. Foker; treasurer, Dr. James R. Fox, all of Minneapolis; and recorder, Dr. Herman E. Drill, Hopkins. Executive board members are Drs. Edwin G. Benjamin and Leonard S. Arling, both of Minneapolis.

Research on Emergency Food Needs.—Minimum food needs in cases of emergency are being studied in a five year research program by the University of Minnesota Laboratory of Physiological Hygiene. Sponsored by the Quartermaster General and Surgeon General of the Army, these new studies are designed to help the Department of Defense plan for military emergencies. Nineteen soldiers from Ft. Lee, Va., have volunteered for rigid discipline and periods of hunger and discomfort in the first of a series of experiments, each lasting six to eight weeks. Circulation tests to be used will dovetail with the main long-term research of the laboratory on heart disease and aging of the blood vessels.

NEBRASKA

Memorial to Dr. Manning.—A public health scholarship fund memorializing the late Dr. Ernest T. Manning of Omaha has been established at the University of Nebraska. Income from the $4,000 fund will provide scholarships for undergraduate students in the university's college of medicine who plan to specialize in the field of public health. Dr. Manning was assistant professor of pathology at the college from 1909 to 1920. He then served in the Omaha Public Health Service and later as public health officer of Omaha city schools. During World War II, he was a part-time member of the university's medical faculty.

NEW JERSEY

Society News.—At the annual fall meeting of the New Jersey Orthopaedic Society in Long Branch, Dr. Henry H. Kessler, Newark, was elected president, Dr. John J. Flanagan, Newark, president-elect, Dr. William Kruger, Newark, secretary, and Dr. Harold T. Hansen, South Orange, treasurer.

Meeting of Chest Physicians.—The New Jersey chapter, American College of Chest Physicians, will meet at the Bonnie Burn Sanatorium, Scotch Plains, Nov. 24, 8:30 p. m. "Mediastinal Tumors" will be presented by Dr. Herbert C. Maier, director of surgery, Lenox Hill Hospital, New York, and discussed by Dr. George N. Sommer, thoracic surgeon, St. Francis and F. W. Donnelly Memorial hospitals, Trenton. A collation will follow.

Fiftieth Anniversary Issue.—The September number of the *Journal of the Medical Society of New Jersey*, the 50th anniversary issue, includes half-century reviews of medicine (Dr. George H. Lathrop, Morristown); surgery (Dr. David B. Allman, Atlantic City); maternal welfare (Dr. Hammell P. Shipps, Camden); otolaryngology (Dr. Henry B. Orton, Newark); pharmacology (Dr. Rowland D. Goodman, Trenton); public health (Dr. Daniel Bergsma, Trenton); and urology (Dr. Clarence R. O'Crowley, Newark); as well as the article, "The Military Role of New Jersey Physicians in the Past Fifty Years" by Dr. Henry A. Brodkin, Newark. Dr. Julius Gerendasy, Elizabeth, contributes an article on the history of the New Jersey Gastroenterological Society, whose 20th anniversary coincides with the journal's 50th.

NEW YORK

Postgraduate Course in Ophthalmology.—The department of ophthalmology of the State University of New York College of Medicine at Syracuse will present its fourth annual postgraduate course in ophthalmology at the Hotel Syracuse, Dec. 11-12. Guest lecturers include Drs. Alan C. Woods, Baltimore, Harold F. Falls, Ann Arbor, Mich., and Hunter H. Romaine and Franklin M. Foote, New York. The tuition fee ($25 payable to the State University of New York College of Medicine at Syracuse) covers tuition, daily luncheons, and dinner Friday night. The course will be limited to 60 members who will be accepted in the order in which applications accompanied by checks are received. Inquiries may be addressed to Dr. Harold H. Joy, 504 State Tower Building, Syracuse.

State Housing for the Handicapped.—Herman T. Stichman, the state housing commissioner, announces that a substantial number of apartments equipped to serve the needs of the physically handicapped (the aged and those orthopedically handicapped) are to be provided in state-aided public housing projects for persons of low income. "New York State has a $735 million slum clearance and public housing fund for families of low income, coupled with cash subsidies of $25 million annually," he said, "and the handicapped and aging are particularly entitled to its benefits." Special installations in state-aided housing projects for the aging include: bathtubs with seats, nonslip bathroom floors, no thresholds, electric instead of gas stoves, cabinets at lower levels, apartments on the sunny side, and extra heat. For those suffering from orthopedic handicaps the special installations will be based on experiments at the Rehabilitation Institute of New York University-Bellevue Medical Center. They include: ramps, living and bedrooms 10% larger than normal public housing standards, nonslip flooring, casement type windows with mechanical operators, high wash basins and kitchen sink counters to permit use by tenant in a wheelchair, electric ranges, and showers in addition to bathtubs.

New York City

Personal.—The American Medical Women's Association has presented a citation to Dr. Ada Chree Reid, retiring editor of the *Journal of the American Medical Women's Association* in appreciation of her outstanding service to the journal and to the advancement of the interests of the association.

Reiss Memorial Lecture.—Dr. Paul Klemperer, pathologist, Mount Sinai Hospital, will deliver the second Herman L. Reiss memorial lecture, "The Anatomic Concept in Pathology," before the New York Institute of Clinical Oral Pathology at the New York Academy of Medicine, Nov. 23, 8:30 p. m.

Course on Physical Therapy.—The Institute of Physical Medicine and Rehabilitation, New York University-Bellevue Medical Center and the New York University school of education are again offering a four week course, "Advanced Physical Rehabilitation Methods for Physical Therapists" (Nov. 23-Dec. 18; Feb. 1-26, 1954; May 2-29), with four points of university credit. Tuition fee is $80; registration fee, $8. Qualified veterans may enroll under the provision of P. L. 346 or P. L. 16. The course, which will cover (1) severe disabilities and their rehabilitation, (2) skills and methods of functional activities, and (3) clinical experience, is open to certified physical therapists who have the approval of the curriculum director. Applications should be submitted to the director, Rehabilitation Courses for Physical Therapists, Institute of Physical Medicine and Rehabilitation, 325 E. 38 St., New York 16.

NORTH CAROLINA

Nuclear Reactor at State College.—Loading of fissionable material in the nation's first university-owned nuclear reactor began at North Carolina State College of Agriculture and Engineering, Raleigh, at 12:59 a. m., Sept. 5. The project was started in June, 1950, when the college, under contract to the Atomic Energy Commission, initiated the design and construction of a low-powered research reactor. The building to house the reactor was completed in May, 1953. One of the major purposes of the reactor will be to supply reactor experience to undergraduate and graduate students in nuclear engineering, a new curriculum initiated by the college in 1950. A program of research on the reactor itself is scheduled for the first year of its operation, after which the emphasis will shift to the use of radiations and radioactive isotopes produced by the reactor.

Death of Professor Bronfenbrenner.—Jacques J. Bronfenbrenner, Ph.D., D.P.H., research professor of microbiology and immunology, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, died Aug. 13 of myocardial infarction. Dr. Bronfenbrenner, born Nov. 20, 1883, in Cherson, Russia, was an assistant at the Imperial University, Odessa, Russia, in 1905, and in 1908 and 1909 was an assistant at the Pasteur Institute, Paris, France. He came to the United States and was naturalized in 1913. From 1909 to 1913 he was a fellow and assistant at the Rockefeller Institute in New York (where he later was an associate fellow, 1923-1928); from 1913 to 1917 Dr. Bronfenbrenner was director of the research and diagnostic laboratories of Western Pennsylvania Hospital in Pittsburgh; and from 1917 to 1923 was assistant professor of preventive medicine and hygiene at Harvard University School of Medicine, Boston. Named head of the department of bacteriology and immunology at Washington University School of Medicine, St. Louis, in 1928, he held that post until his retirement in 1952, when he joined the Bowman Gray faculty. Dr. Bronfenbrenner, who received the Pasteur award of the Illinois Bacteriologists in 1950, served as president of the American Association of Immunologists from 1942 to 1946. A son, Dr. Jack Bronfenbrenner, is a physician in Benton Harbor, Mich.

OKLAHOMA

Lecture on Cancer.—Dr. J. Samuel Binkley, Oklahoma City, will address the Tulsa Academy of General Practice, Nov. 23, at Hotel Tulsa on indications for the early surgical treatment of cancer. All physicians are invited. Reservations for dinner, 6:30 p. m., may be made by calling 2-5904. The scientific program will be at 8 p. m.

Personal.—Dr. Hiram G. Campbell, Tecumseh, who at the age of 80 completed 50 years in the practice of medicine, was awarded a 50 year pin at a recent meeting of the Pottawatomie County Medical Society. Dr. Campbell is a former president of the Pottawatomie County Medical Society.——Dr. Othel J. Gee, Oklahoma City, has been elected National Commander of the Army and Navy Legion of Valor of the United States of America at the 63rd annual reunion in Lexington, Ky. Membership in the legion of valor is restricted to holders of the Congressional Medal of Honor, the Distinguished Service Cross, or the Navy Cross.——Dr. Edward C. Reifenstein Jr., Oklahoma City, has been appointed director of biological and therapeutic research for the Schering Corporation. For the past two and one-half years he has served as director of the Oklahoma Medical Research Institute and Hospital in Oklahoma City. Charles D. Kochakian, Ph.D., formerly associate director, has been appointed co-ordinator of research of the Oklahoma Medical Research Foundation, Oklahoma City, to replace Dr. Reifenstein.——Dr. Stewart G. Wolf Jr., professor of medicine, University of Oklahoma School of Medicine, Oklahoma City, has assumed, in addition to his regular duties, the responsibilities of supervisor of clinical activities in the Oklahoma Medical Research Hospital.

PENNSYLVANIA

Rabies in Bats.—According to the Department of Health, Education, and Welfare, U. S. Public Health Service, E. J. Witte, veterinarian, Pennsylvania Department of Health, reported that rabies infection in a bat has been confirmed by the State Bureau of Animal Industry. On Sept. 29 the bat attacked a woman living in the south central part of the state. The bat was captured, and its brain tissue showed suggestive signs of rabies, which were confirmed by animal inoculation. Studies were in progress to ascertain the extent of rabies in the area where the bat was caught.

Philadelphia

Hospital News.—The 67th annual banquet of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held Dec. 1 in the Penn-Sheraton Hotel, 39th and Chestnut Sts. For reservations, address Dr. John D. Corbit Jr., 3717 Chestnut St., Philadelphia 4.

Philips Lecture.—Dr. Haven Emerson, emeritus professor of public health, Columbia University College of Physicians and Surgeons, New York, will discuss "Preventive Medicine and Public Health" at Roberts Hall, Haverford College, Nov. 24, 11 a. m. This is one of the lectures in the William Pyle Philips series, "New Frontiers in Medicine."

Pittsburgh

Narcotic Violation.—Dr. Abraham J. Ishlon, 1910 Carson St., pleaded guilty in the U. S. District Court of Pittsburgh to a charge of violating the Federal narcotic law. On Sept. 14 he received a sentence of two years on probation.

Lectures in Ophthalmology.—Special lectures in the basic science of ophthalmology will be given in evening sessions throughout the school term of the University of Pittsburgh School Medicine by the staff of the Eye, Ear, Nose and Throat Hospital. These lectures are free to physicians. The schedule may be obtained from Dr. Murray F. McCaslin, chief, eye service, Eye, Ear, Nose and Throat Hospital.

SOUTH DAKOTA

Fifty Year Club.—Dr. Robert J. Jackson, Rapid City, recently became the 18th South Dakota physician to receive membership in the South Dakota State Medical Association's 50 year club. Dr. Jackson served as county coroner from 1903 to 1923 and as mayor of Rapid City for two years.

University News.—Rubert S. Anderson, Ph.D., resigned Oct. 1 as professor of physiology and pharmacology, University of South Dakota School of Medical Sciences, Vermillion, to accept appointment at the Army Chemical Center, Bethesda, Md., where he will be on the medical laboratory staff as a civilian in research work. He will also teach graduate students from the University of Maryland School of Medicine and College of Physicians and Surgeons in Baltimore.

VIRGINIA

Dr. Ware Honored.—Dr. H. Hudnall Ware Jr., head of the department of obstetrics at the Medical College of Virginia, Richmond, was honored on Sept. 18 by a group of his former students on the 25th anniversary of his joining the college staff. At a dinner tendered Dr. and Mrs. Ware, a scholarship and student loan fund was announced in his honor.

Public Relations Conference.—The public relations committee of the Medical Society of Virginia will present a combination public relations and public information conference Nov. 24 at the Hotel John Marshall in Richmond. The morning will be devoted to the woman's auxiliary. The afternoon program will be of a public information nature, and the problems of the medically indigent and the chronically ill will be considered. Participating will be representatives from the League of Virginia Counties, Virginia Hospital Association, State Health Department, State Welfare Department, Virginia Council on Health and Medical Care, and other interested groups.

WEST VIRGINIA

Past Presidents in House of Delegates.—Under an amendment affecting the service of past presidents as members of the house of delegates, adopted at the annual meeting of the West Virginia State Medical Association in White Sulphur Springs, all living past presidents, and the incumbent, Dr. James S. Klumpp, Huntington, will continue to serve as members of the house of delegates as long as they live; but presidents elected in 1953 and for the years following will be limited to three years of service in the house (the year they serve as president and the two years following).

HAWAII

Personal.—Dr. Walter B. Quisenberry of the Department of Health, Territory of Hawaii, Honolulu, recently returned from the British Isles, where he attended the annual meeting of the British Medical Association in Cardiff, Wales, as the official AMA delegate. Dr. Quisenberry participated in a panel on cancer and the community.

Leprologist Wanted.—A medical director is needed for Kalaupapa Settlement, Molokai (salary, $8,800-$9,800 with perquisites). The following training and experience are required: (1) four years of experience as a physician, of which two years shall have involved treatment of Hansen's disease, and graduation from a medical school of recognized standing, including, or supplemented by, one year of internship in a recognized general hospital; or (2) any equivalent combination of experience and training. The physician must be licensed to practice medicine in the Territory of Hawaii. Address the Board of Health, Box 3378, Honolulu.

GENERAL

Multiple Sclerosis Grant.—A grant of $34,354 has been awarded to the National Multiple Sclerosis Society by the Kresge Foundation, in memory of the late Paul W. Voorhies, former president of the foundation. The grant will further the multiple sclerosis research project at the New York University-Bellevue Medical Center, already established by the society and to which it has allocated over $100,000.

Association of Medical Clinics.—At the annual meeting in Chicago the American Association of Medical Clinics installed Dr. Wayne Gordon, Billings Clinic, Billings, Mont., as president, named Dr. J. C. Thomas Rogers, Carle Hospital Clinic, Urbana, Ill., vice-president and president-elect, and reelected Dr. Arthur H. Griep, Welborn Clinic, Evansville, Ind., secretary-treasurer. The next annual meeting will be held in New Orleans.

Tuberculosis Achievement Awards.—The Variety Club-Will Rogers Hospital, Saranac Lake, N. Y., announces that an annual achievement awards program will be initiated as a stimulus in the fight against tuberculosis and other chest diseases. The first presentation of the annual awards will be made at the 20th annual meeting of the American College of Chest Physicians in San Francisco, June 17-20, 1954. Nominees for the awards will be selected by the college. A committee of judges will determine eligibility. Sculptured bronze plaques and cash honorarium will be awarded in each of the three fields: the greatest discovery in research, the most important medical contribution, and the highest achievement in surgery of chest diseases.

National Advisory Committee Meeting in St. Louis, Dec. 2.—The National Advisory Committee to the Selective Service System is meeting in St. Louis at the time of the A. M. A. Clinical Meeting. The committee would appreciate it if any chairman or member of a state or local committee who happens to be in attendance at the Clinical Meeting would meet with the national committee at 2 p. m., on Wednesday, Dec. 2. The place of the meeting will be announced later.

The advisory committee, 451 Indiana Ave., N.W., Washington 25, D. C., would appreciate hearing from those who expect to be present so that the necessary arrangements can be made for the proper-sized meeting room. It will not be possible for travel to be reimbursed by the government because of budgetary limitations. The committee hopes, however, that there will be a number of chairmen and committee members who will be present.

American Foundation for Allergic Diseases.—Dr. Horace S. Baldwin, New York, is president of the newly formed American Foundation for Allergic Diseases, which has headquarters at 525 Lexington Ave., at 49th St., New York. This voluntarily supported, nonprofit organization, was created after a fact-finding survey by members of the executive committee of the American Academy of Allergy and the board of regents of the American College of Allergists. The foundation will promote through public education an understanding of the problems of allergic diseases, inform and educate the medical profession in the problems of allergy, cooperate with medical institutions, hospitals, and other organizations in the development of facilities for the treatment and prevention of allergic diseases, and finance facilities for research in allergic diseases, including fellowships and residencies. The other officers of the foundation are: Dr. J. Warrick Thomas, Richmond, Va., vice-president; Dr. Bret Ratner, New York, secretary; and Dr. Theodore L. Squier, Milwaukee, treasurer.

Symposium on Glutathione.—A symposium on glutathione research, sponsored by the National Science Foundation and the Office of Naval Research, Washington, D. C., and administered by Columbia University, New York, is being held in Ridgefield, Conn., Nov. 20-21. The role of glutathione in enzyme actions, growth, and the creation of body energy and as a therapeutic agent against radiation damage and certain diseases, such as diabetes, will be considered. Five sessions have been scheduled to discuss organic chemistry of sulfhydryl compounds and glutathione, biosynthesis of glutathione and its role in peptide synthesis, methods for determination of glutathione, glutathione as a coenzyme, and relation of glutathione to metabolism and disease. Physicians directing the symposium include Drs. Arnold Lazarow, Cleveland, Ephraim Racker, New Haven, Conn., and Heinrich Waelsch, New York.

Red Cross Adopts Changes in First Aid Techniques.—Two major changes in first aid care, adopted on recommendations by the committee on surgery of the division of medical sciences, National Research Council, are announced in a new supplement to the American Red Cross First Aid Textbook. It is now recommended that a tourniquet be applied close to the wound, with unbroken skin between it and the wound; remain undisturbed until released by a physician; and be used only for severe life-threatening hemorrhage that cannot be controlled by other means. In frostbite or prolonged exposure to cold, rapid warming is recommended instead of the previously approved gradual thawing out of a frozen part in cool water or in a cool room. The victim is to be brought into a warm room as quickly as possible and placed in a tub of warm, not hot, water or wrapped in warm blankets. Rubbing of the frozen part is not recommended, but, after the part is rewarmed, the victim should be encouraged to exercise fingers and toes. The supplement includes the technique for the back-pressure-arm-lift method of artificial respiration, adopted by the Red Cross in 1951. Free copies of the supplement may be obtained through local Red Cross chapters.

Surgeons Meeting in Los Angeles.—At a regional meeting of the International College of Surgeons at the Ambassador Hotel, Los Angeles, Nov. 28-29, a panel discussion of diagnostic problems, surgical management, and preoperative and postoperative care of the acute abdomen will be held Saturday. Dr. Arnold S. Jackson, Madison, Wis., will preside at the afternoon session, when the presentations will include "Postgastrectomy Syndromes," "The Pathological Intrahepatic Gallbladder and Related Anomalies," "Considerations of Nonmalignant Skin Tumors," and "Dupuytren's Contracture." Sunday morning Dr. Joseph M. de los Reyes, Los Angeles, will preside. Presentation of "Total Gastrectomy for Cancer" and "Anesthesia for Chest and Transthoracic Abdominal Surgery" will be followed by a panel discussion, "Chest and Transthoracic Abdominal Surgery and Anesthesia." Sunday afternoon Dr. Henry W. Meyerding, Rochester, Minn., will preside. "Transposed Flaps in the Repair of Surface Defects," "Your Hearing Impairment," "Precancerous Lesions Encountered in Routine Anorectal Examination," "Abdominal Symptoms of Genitourinary Pathology," and "Tumors of the Neck" are scheduled. The meeting is open to the medical profession.

Cancer Grants.—A grant of $79,110 to Columbia University College of Physicians and Surgeons, New York, for six projects under the guidance of Dr. Alfred A. Gellhorn, director of the Institute of Cancer Research, was the principal allocation among $181,670 in September grants made to eight institutions in New York City and three states by the Damon Runyon Memorial Fund for Cancer Research. Fellowships totaling $24,400 were approved for six research scientists engaged in various projects of cancer study. The Memorial Center for Cancer and Allied Diseases was the recipient of three individual grants: (1) $22,000 for a project under the direction of Dr. James J. Nickson and John S. Laughlin, Ph.D., entitled "Studies to Evaluate the Role of High Energy Radiation in Cancer Patients"; (2) $9,500 for a new project, "Quantitative Analysis of the Cell by Interference Microscopy," undertaken by Dr. Robert C. Mellors; and (3) $10,000 to Dr. Olof H. Pearson to study "The Effects of Altered Hormonal Environment on the Growth of Carcinoma of the Breast in Women." University of Oregon Medical School, Portland, received $17,000 for a study to be carried on by Dr. Thomas B. Fitzpatrick, Dr. Aaron B. Lerner, and Howard S. Mason, Ph.D., entitled "Metabolism of Melanomas." Two new institutions are included in the allocations: Chicago Medical School, in the amount of $4,860 for a study "Metastatic Dissemination of Tumors Induced by Cortisone" and New Mexico Highlands University, Las Vegas, N. Mex., $4,800 for a projected study, entitled "Synthesis of Some Imidazo (c) Pyridines as Potential Purine Antagonists." The latest grants brought the total money distributed to $7,246,786.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Federation for Clinical Research, Eastern Section, Amphitheater, Children's Medical Center, Boston, Jan. 4. Dr. Walter Judson, Evans Memorial Hospital, Boston, Chairman.

American Laryngological, Rhinological and Otological Society:

- Eastern Section, Waldorf-Astoria, New York, Jan. 8. Dr. Francis W. Davison, Danville, Pa., Chairman.
- Southern Section, Brown Hotel, Louisville, Ky., Jan. 16. Dr. Lester A. Brown, 490 Peachtree St., N.E., Atlanta 3, Ga., Chairman.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

National Society for the Prevention of Blindness, New York, Dec. 18. Dr. Franklin M. Foote, 1790 Broadway, New York 19, Executive Director.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Eastern Pennsylvania, Philadelphia, Jan. 15. Dr. Thomas M. McMillan, 330 S. Ninth St., Philadelphia 7, Governor.
- Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East Ann St., Ann Arbor, Governor.
- North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Western Surgical Association, The Drake, Chicago, Dec. 3-5. Dr. Michael Mason, 154 East Erie St., Chicago 11, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. MacRae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Diseases of the Chest, Barcelona, Spain, Oct. 4-8, 1954. Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, *Illinois, Executive Secretary.*

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6ᵉ, France, Secretary.

International Congress of the History of Medicine, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Instituto di Storia della Medicine, Citta Universitaria, Rome, Italy.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni Venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of Industrial Medicine, Naples, Italy, Sept. 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, Sept. 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, Sweden, Secretary-General.

International Congress of International College of Surgeons, Sao Paulo, Brazil, April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake Shore Drive, Chicago. Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress of Nutrition, Amsterdam, Netherlands, Sept. 14-18, 1954. For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, Netherlands.

International Congress on Obstetrics and Gynecology, Geneva, Switzerland, July 26-31, 1954. Dr. H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, President.

International Congress of Ophthalmology, University of Montreal and McGill University, Montreal, Canada, Sept. 10-11, 1954, and Waldorf-*Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954.* Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minnesota, U. S. A., *Secretary-General.*

International Congress of Orthopedic Surgery and Traumatology, Berne, Switzerland, Aug. 30-Sept. 3, 1954. For information write: Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

International Congress of Psychology, Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., U. S. A.

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Poliomyelitis Congress, Rome, Italy, Sept. 6-10, 1954. Mr. Stanley E. Henwood, 120 Broadway, New York 5, N. Y., U. S. A., Executive Secretary.

International Society of Blood Transfusion, Paris, France, Sept. 12-19, 1954. For information write: Colonel Julliard, Societe Internationale de Transfusion Sanguine, 53 Boulevard Diderot, Paris 12ᵉ, France.

International Society for Cell Biology, Leiden, Netherlands, Sept. 2-9, 1954. Professor *Peter J. Gaillard,* University of Leiden, Leiden, Netherlands, Secretary.

International Society of Geographical Pathology, Washington, D. C., U. S. A., *Sept. 6-10, 1954.* Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro, Medico, Caracas, Venezuela, Secretary-General.

Latin American Congress of Physical Medicine, Medellin, Columbia, South America, Feb. 25-20, 1954. Dr. Cassius Lopez de Victoria, 176 East 71st St., New York 21, N. Y., U. S. A., Executive Director.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954. Dr. Pedro Hernandez Gonzalo, 8 No. 358, Vedado, Havana, Cuba, General Secretary.

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Pan-Pacific Surgical Congress, Honolulu, Hawaii, Oct. 7-18, 1954. Dr. F. J. Pinkerton, Suite 7, Young Bldg., Honolulu 13, Hawaii, Director General.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. *N. J. Conan Jr., Department of Internal Medicine,* Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Sectional Meeting, American College of Surgeons, London, England, *May 17-19, 1954. Dr. Michael L. Mason,* 40 East Erie St., Chicago 11, *Ill., U. S. A., Secretary.*

South American Congress of Angiology, Sao Paulo, Brazil, July 1954. For information write: Dr. Rubens Carlos Mayall, Rua Senador Vergueiro 73, Rio de Janeiro, Brazil, S. A.

World Congress of Cardiology, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-17, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* Various Centers, July 16. Sec., Dr. Curtiss B. Hickox, 80 Seymour St., Hartford 15.

American Board of Neurological Surgery: *Oral.* Chicago, May or June. Final date for filing application is Jan. 15. Sec., Dr. Leonard T. Furlow, 600 S. Kingshighway, St. Louis 10.

American Board of Neurology and Psychiatry: *Psychiatry and Neurology.* Dec. 14-15. Applications no longer being accepted. Chicago, April 29-30. Final date for filing application is Feb. 1. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Obstetrics and Gynecology: Written examination and review of case histories for all candidates will be held in various cities of the United States, Canada, and military centers outside the continental United States on Feb. 5. Case abstracts are to be sent by the candidate to the Secretary as soon as possible after receiving notification of eligibility to the Part I written examination. *Oral.* Chicago, Oct. 1. Application for reexamination in Part II must be made prior to Feb. 1 of any year. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written.* Various Centers, January 25-26, 1954. Final date for filing applications was July 1. *Practical.* San Francisco, June 25-29; New Orleans, Feb. 5-11, 1955. Final date for filing application for 1955 written examination is July 1. Sec., Dr. *Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.*

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 20-22. Final date for filing application was August 15. Final date for filing application for Part I is Nov. 30. Sec., Dr. Harold A. Sofield, 122 S. Michigan Ave., Chicago 3.

American Board of Obstetrics: *Written.* Selected Places, Jan. 15. This is the only written examination which will be given during 1954. *Oral.* Washington, D. C., Feb. 19-21; Des Moines, March 19-21; New York City, May 1-3; San Francisco, June 25-27; Chicago, Oct. 8-10 and New Haven, December.

American Board of Radiology: *Oral. Radiology, Roentgenology, Diagnostic Roentgenology and Therapeutic Radiology.* Chicago, Dec. 6-11. Final date for filing application was July 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

American Board of Urology: *Oral-clinical and pathology.* Chicago, Feb. 17-20. Sec., Dr. Harry Culver, 30 Westwood Road, Minneapolis 16.

DEATHS

Henry, Myron Ormell ⊕ Minneapolis; born in Minneapolis Dec. 28, 1893; University of Minnesota Medical School, Minneapolis, 1921; clinical assistant professor of surgery at his alma mater; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association, Clinical Orthopaedic Society of which he was secretary-treasurer, and the American Academy of Orthopaedic Surgeons, of which he was secretary; fellow of the American College of Surgeons; affiliated with Abbott and Northwestern hospitals; member of the visiting staffs, St. Barnabas and Asbury hospitals; consultant in orthopedic surgery, Glen Lake Sanatorium in Oak Terrace; died in Northwestern Hospital, Aug. 31, aged 60, of recurrent cerebral thrombosis and hypertensive cardiovascular disease.

Lawless, Ambrose Thomas, Syracuse, N. Y.; born in Marcellus Falls, N. Y., March 22, 1885; Syracuse University College of Medicine, 1910; clinical professor emeritus of surgery at his alma mater, now known as State University of New York College of Medicine at Syracuse; specialist certified by the American Board of Surgery; served during World War I; during World War II served on a county draft board, for which he was awarded a citation; past president of the Onondaga County Medical Society; senior attending surgeon and past president of the staff, St. Joseph's Hospital, where he died Sept. 13, aged 68, of gastric hemorrhage, cirrhosis of the liver, and uremia.

Galvin, Thomas Keough ⊕ Baltimore; born in Baltimore in 1891; College of Physicians and Surgeons, Baltimore, 1915; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; clinical professor of gynecology at the University of Maryland School of Medicine and College of Physicians and Surgeons; served during World War I; affiliated with Mercy and St. Joseph's hospitals as gynecologist-in-chief; gynecologist, Hospital for the Women of Maryland; on the visiting staffs of the Union Memorial and St. Agnes' hospitals; died Sept. 19, aged 61, of coronary thrombosis.

Engman, Martin Feeney ⊕ St. Louis; University of the City of New York Medical Department, 1891; professor emeritus of clinical dermatology at Washington University School of Medicine; an Associate Fellow of the American Medical Association; member of the American Dermatological Association, of which he was past president; specialist certified by the American Board of Dermatology and Syphilology; affiliated with Barnard Free Skin and Cancer Hospital, of which he was founder, St. Luke's Hospital, and Barnes Hospital; died Oct. 12, aged 85, of acute heart failure.

McPherson, Samuel Dace ⊕ Durham, N. C.; born April 20, 1873; University of Maryland School of Medicine, Baltimore, 1903; past president of the Durham-Orange Counties Medical Society; for many years chairman of the county board of health; specialist certified by the American Board of Otolaryngology; fellow of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; founder of the McPherson Hospital; on the honorary staff of the Lincoln Hospital and the Watts Hospital, where he died Sept. 12, aged 80, of arteriosclerosis.

Wells, Fred Lloyd ⊕ Des Moines, Iowa; Bellevue Hospital Medical College, New York, 1888; past president of the Association of Life Insurance Medical Directors; for many years associated with the National Travelers Casualty Company, the Interstate Assurance Company, and the Iowa State Traveling Men's Association, serving the latter two until the time of his death; from 1912 to 1936 medical director of the Equitable Life Insurance Company of Iowa; died in the Iowa Methodist Hospital Sept. 17, aged 85, of empyema of the gallbladder.

Ahrens, Harvey, Des Moines, Iowa; Illinois Medical College, Chicago, 1903; died June 15, aged 77, of acute circulatory failure.

Duncan, Melvin Dewey ⊕ Murfreesboro, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1926; formerly mayor; member of the board of education; affiliated with Howard County Memorial Hospital in Nashville; died Sept. 20, aged 55, of coronary thrombosis.

Dunning, Edgar Clarence, Highland Park, Mich.; Chicago Homeopathic Medical College, 1901; died Aug. 18, aged 82, of bronchopneumonia.

Early, William Leyton, Wolftown, Va.; Medical College of Virginia, Richmond, 1898; affiliated with University of Virginia Hospital, Charlottesville, where he died Sept. 25, aged 76, of lymphoblastoma.

Ewing, George Winburn ⊕ Peabody, Mass.; Baltimore University School of Medicine, 1899; on the staff of the Josiah B. Thomas Hospital; served on the staff of the North Shore Baby Hospital in Salem and the Essex County Tuberculosis Sanatorium in Middleton; died Sept. 22, aged 76, of cancer.

Fedde, Gabriel Martin Nathanael ⊕ Staten Island, N. Y.; Cornell University Medical College, New York, 1912; affiliated with Richmond Memorial Hospital; for many years a medical missionary to China; died Oct. 7, aged 69, of arteriosclerosis.

Flothow, Paul George ⊕ Seattle; University of Pennsylvania School of Medicine, Philadelphia, 1923; member of the Pacific Coast Surgical Association and the North Pacific Surgical Association; fellow of the American College of Surgeons; certified by the National Board of Medical Examiners; served during World War I; member of the staffs of the Providence, Swedish, Doctors, Seattle General, Children's Orthopedic, Maynard, and Columbus hospitals; died Sept. 21, aged 56, of coronary disease.

Foley, Harry Thomas ⊕ Pittsburgh; University of Pittsburgh School of Medicine, 1929; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served during World War II; consulting cardiologist, Memorial Hospital, Monongahela; affiliated with Presbyterian and Woman's hospitals; died Sept. 20, aged 48, of coronary occlusion.

Folsom, Charles W., Conway, Miss. (licensed in Mississippi in 1906); died in Tallahassee, Fla., Aug. 4, aged 85, of uremia.

Frazier, Harold Langford ⊕ Chicago; Rush Medical College, Chicago, 1901; an Associate Fellow of the American Medical Association; on the staff of the Swedish Covenant Hospital, where he died Oct. 3, aged 75, of prostatic carcinoma.

Fry, John Lewis, Kalona, Iowa; Northwestern University Medical School, Chicago, 1911; member of the school board; on the staff of the Mercy Hospital in Iowa City; died in Columbus Junction Sept. 15, aged 71, of cerebral hemorrhage and arteriosclerosis.

Fulton, Gavin ⊕ Louisville, Ky.; University of Louisville (Ky.) Medical Department, 1894; served on the staffs of the Kosair Crippled Children Hospital, Children's Hospital, and Norton Memorial Infirmary, where he was past president of the staff and where he died Sept. 9, aged 80, of fracture of the hip received in a fall and cerebrovascular accident.

Gilliland, Caroline Jane ⊕ Sharon, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1906; an Affiliate Fellow of the American Medical Association; served on the staff of the Sharon General Hospital; died in Mercer (Pa.) Sanitarium Sept. 2, aged 87, of senility.

Gilmore, Lewis Daniel, Pittsfield, N. H.; Tufts College Medical School, Boston, 1913; died Aug. 21, aged 62, of coronary thrombosis.

⊕ Indicates Member of the American Medical Association.

Hagood, John W. ⊕ Evergreen, Ala.; Medical College of Alabama, Mobile, 1898; died July 15, aged 78, of cerebral hemorrhage, hypertension, and arteriosclerosis.

Hatfield, Richard Henry ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1902; veteran of the Spanish-American War; affiliated with Prospect Heights Hospital for many years; died in Dumont, N. J., Sept. 21, aged 74, of coronary thrombosis.

Heilesen, William Edward, Iroquois, S. D.; University of Nebraska College of Medicine, Omaha, 1929; died in Prescott, Wis., June 13, aged 51.

Higgins, Martin Andrew, Rye, N. H.; Baltimore Medical College, 1907; died Aug. 18, aged 69, of acute coronary occlusion.

Highsmith, Luther Byrl, Flat Rock, Ill.; Loyola University School of Medicine, Chicago, 1916; died in Lawrence County Memorial Hospital in Lawrenceville, Oct. 6, aged 66, of meningioma and phlebothrombosis of the left main pulmonary artery.

Hoitt, George Barnard ⊕ Manchester, N. H.; Dartmouth Medical School, Hanover, N. H., 1899; died Sept. 14, aged 83, of arteriosclerosis.

Isaacson, Barney, New York City; University and Bellevue Hospital Medical College, New York, 1921; served on the staff of the Bronx Hospital; died Aug. 28, aged 56, of cerebral hemorrhage.

James, Maurice Clayton ⊕ Columbus, Neb.; Jefferson Medical College of Philadelphia, 1914; fellow of the International College of Surgeons; past president of the Platte County Medical Society; served during World War I; affiliated with St. Mary and Lutheran hospitals; died Sept. 11, aged 69, of carcinoma of the stomach.

Kenney, Stephen A. ⊕ Valley Falls, R. I.; College of Physicians and Surgeons, Baltimore, 1899; an Associate Fellow of the American Medical Association; past president of the Pawtucket Medical Association; for many years health officer for the town of Cumberland; died Sept. 14, aged 77, of cerebral arteriosclerosis.

Kirk, Marion Singleton, Hagood, S. C.; Medical College of the State of South Carolina, Charleston, 1895; died Sept. 13, aged 83, of coronary thrombosis.

Klopstock, Erich, Forest Hills, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Germany, 1922; died May 29, aged 55.

Kolb, Thomas Victor ⊕ Litchfield, Ohio; Ohio State University College of Medicine, Columbus, 1934; member of the American Academy of General Practice; served during World War II; affiliated with Lodi (Ohio) Community Hospital, where he died Sept. 20, aged 49, of subarachnoid hemorrhage.

Koons, Charles Edward ⊕ Creal Springs, Ill.; St. Louis University School of Medicine, 1904; died in Van Buren, Mo., Aug. 9, aged 74.

Kretlow, Fred A. ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1924; served during World War II; on the staff of the Misericordia Hospital for many years; died in Columbus Hospital Sept. 20, aged 54, of coronary thrombosis.

Latz, Benno Ernst, New York City; Christian-Albrechts-Universität Medizinische Fakultät, Kiel, Germany, 1903; died Oct. 2, aged 75, of coronary thrombosis.

Lauder, Clark Hays ⊕ Monrovia, Calif.; State University of Iowa College of Medicine, Iowa City, 1909; member of the Pacific Coast Oto-Ophthalmological Society; died Sept. 29, aged 69, of coronary thrombosis.

Lawson, Sidney B. ⊕ Logan, W. Va.; Baltimore Medical College, 1894; for many years member of the Logan County Court; at one time mayor of Williamson; co-founder of the Hatfield-Lawson Hospital; past president and for many years director of the old First National Bank of Logan; died in Delray Beach, Fla., Oct. 9, aged 86, of asthma and heart disease.

Lazarus, George Fred, Mattituck, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1894; on the staffs of the Carson Peck Memorial and Prospect Heights hospitals in Brooklyn; died Oct. 4, aged 84, of a heart attack.

Lewis, Andrew Llewellyn ⊕ Sumner, Mo.; Marion-Sims College of Medicine, St. Louis, 1898; an Associate Fellow of the American Medical Association; died in Brookfield Aug. 25, aged 86, of uremia, following fracture of right hip.

Lindsay, Harry Clubb Lodge ⊕ Pasadena, Calif.; Western University Faculty of Medicine, London, Ontario, Canada, 1909; member of the American Academy of Dermatology and Syphilology; affiliated with St. Luke and Huntington Memorial hospitals; died Sept. 9, aged 70, of arteriosclerosis.

McClure, William Charles ⊕ Oklahoma City, Okla.; University of Oklahoma School of Medicine, 1936; assistant professor of medicine at his alma mater; during World War II served with the marines in the Pacific, earning the Bronze Star for bravery under enemy fire and was awarded the Purple Heart; affiliated with St. Anthony Hospital; died in Panhandle, Texas, Sept. 24, aged 44, of injuries received in an automobile accident.

McDevitt, Bernard J. ⊕ Mount Carmel, Pa.; Temple University School of Medicine, Philadelphia, 1910; past president of the Northumberland County Medical Society; died Sept. 16, aged 84, of arteriosclerosis.

McDowell, James Fredrick ⊕ Birmingham, Ala.; University of Pennsylvania School of Medicine, Philadelphia, 1934; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; served during World War II; assistant professor of obstetrics at the Medical College of Alabama; affiliated with Jefferson-Hillman Hospital, where he died Oct. 4, aged 43, of acute myocardial infarction and coronary sclerosis.

McManus, James William ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1927; past president of the Brooklyn Urological Society; served during World War II; affiliated with Coney Island, St. Catherine's, and Caledonian hospitals and the Midwood Hospital, where he died Sept. 23, aged 51, of coronary thrombosis.

MacVeany, Arthur Patchen ⊕ Miami, Fla.; Columbia University College of Physicians and Surgeons, New York, 1927; certified by the National Board of Medical Examiners; died Sept. 22, aged 57, of acute myocardial infarction and arteriosclerosis.

Magargee, George W., Medina, Ohio; Western Reserve University Medical Department, Cleveland, 1904; died Sept. 30, aged 76.

Marcus, Daniel B. ⊕ Detroit; Wayne University College of Medicine, Detroit, 1932; affiliated with the Grace Hospital, where he died Sept. 26, aged 45, of uremia.

Markel, James Clyde ⊕ Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1904; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; affiliated with Southside and Eye and Ear hospitals; died Oct. 1, aged 75, of cancer of the colon.

Mercer, William F., Richmond, Va.; Medical College of Virginia, Richmond, 1882; formerly on the faculty of his alma mater; past president of the Richmond Academy of Medicine; died Sept. 4, aged 91.

Miller, John Hume, Philadelphia; Jefferson Medical College of Philadelphia, 1903; died in Charleston, S. C., Sept. 16, aged 76.

Moore, Joseph G. ⊕ Birmingham, Ala.; Birmingham Medical College, 1911; died July 20, aged 65, of acute coronary thrombosis.

Murphy, Frank Augustine ⊕ Taunton, Mass.; Tufts College Medical School, Boston, 1902; served during World War I; for many years school physician of Taunton; died Aug. 24, aged 76.

Murrell, Charles Milton ⊕ Sherrard, Ill.; Hospital College of Medicine, Louisville, Ky., 1903; served during World War I; affiliated with St. Anthony's Hospital in Rock Island, Mercer County Hospital in Aledo, and Moline Public Hospital in Moline, where he died Sept. 28, aged 76, of congestive heart failure.

Nash, William Harmon ⊕ Shelbyville, Ky.; University of Louisville Medical Department, 1912; served in France during World War I; on the staff of the King's Daughters' Home for Incurables; for many years affiliated with Old Masons Home; died Sept. 14, aged 65, of coronary occlusion and tuberculosis of the left ankle.

Nichols, David C., Stamps, Ark.; Gate City Medical College, Dallas, Texas, 1904; served as mayor; died Sept. 8, aged 88, of heart failure.

Norman, J. Standing, Gastonia, N. C.; University of Maryland School of Medicine, Baltimore, 1909; affiliated with Gaston Memorial and Gaston County Negro hospitals; died Oct. 6, aged 76, of carcinomatosis.

O'Dell, Lester Ely ⊕ Chicago; the Hahnemann Medical College and Hospital, Chicago, 1906; died in the Presbyterian Hospital Oct. 13, aged 72, of myocardial infarction and coronary heart disease.

Orr, William Law, Matthews, N. C.; North Carolina Medical College, Charlotte, 1914; died in the Presbyterian Hospital, Charlotte, Aug. 9, aged 63, of arteriosclerotic cardiovascular disease.

Ortman, John Wessel, St. Paul; Creighton University School of Medicine, Omaha, 1924; died in the Ancker Hospital Aug. 9, aged 57, of cerebral hemorrhage and hypertension.

Papay, Thomas A., Altoona, Pa.; Georgetown University School of Medicine, Washington, D. C., 1952; interned at Altoona Hospital; killed July 30, aged 32, when his car plunged over an embankment near Altoona.

Parker, Merrill Olmsted ⊕ Auburn, N. Y.; Syracuse University College of Medicine, 1919; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; served during World Wars I and II; formerly on the staff of the St. Lawrence State Hospital in Ogdensburg; on the consulting staff of the Willard (N. Y.) State Hospital; affiliated with the Mercy Hospital and the Auburn Memorial Hospital, where he died Sept. 10, aged 64, of coronary disease.

Pavlo, Samuel George ⊕ Malden, Mass.; Tufts College Medical School, Boston, 1911; member of the New England Obstetrical and Gynecological Society; affiliated with the Melrose (Mass.) Hospital, where he was president of the staff; died Sept. 26, aged 70.

Pearce, Charles Tabb ⊕ Cincinnati; University of the City of New York Medical Department, 1892; served on the staffs of the Cincinnati General and Good Samaritan hospitals; died Oct. 31, aged 82, of perforated duodenal ulcer.

Penrose, Thomas William, Philadelphia; Jefferson Medical College of Philadelphia, 1906; affiliated with the Veterans Administration; died in the U. S. Naval Hospital Sept. 9, aged 73, of carcinoma of the pancreas.

Peters, Charles Edward ⊕ Hayward, Calif.; Starling-Ohio Medical College, Columbus, 1912; member of the Radiological Society of North America; affiliated with the Hayward Hospital; died Aug. 1, aged 64, of coronary occlusion.

Phillips, Alexander Harold ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1914; member of the staff of the Walther Memorial Hospital, where he died Oct. 7, aged 70.

Phillips, Claude Belford ⊕ Collingswood, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1922; died in Our Lady of Lourdes Hospital in Camden, Sept. 1, aged 62, of cerebral hemorrhage.

Powers, Emory Byron, Vaucluse, Va.; University of the South Medical Department, Sewanee, Tenn., 1904; for many years practiced in Winchester, where he served on the staff of Winchester Memorial Hospital; died Sept. 25, aged 74, of cerebral hemorrhage.

Ray, George Lewis ⊕ Portland, Ore.; University of Louisville (Ky.) School of Medicine, 1940; served during World War II; was shot and killed Sept. 25, aged 39.

Reese, Leroy Joseph ⊕ Bolivar, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1910; died Sept. 9, aged 66, of coronary occlusion.

Robertson, Edd Lafayette, Fort Lauderdale, Fla.; University of Nashville (Tenn.) Medical Department, 1899; died in the Veterans Administration Hospital in Coral Gables, Aug. 31, aged 78, of ruptured abdominal aortic aneurysm with hemorrhage.

Rochford, Richard Augustine, Springfield, Mass.; Harvard Medical School, Boston, 1914; fellow of the American College of Surgeons; served overseas during World War I; for many years a member of the board of health; later police commissioner; consultant at Westfield (Mass.) State Sanatorium; for many years affiliated with Mercy Hospital, where he was president of the staff and where he died Sept. 10, aged 64, of uremia and glomerulonephritis.

Rodenbeck, Frank ⊕ Arcadia, Ind.; Medical College of Indiana, Indianapolis, 1904; died Sept. 17, aged 71, of dissecting aneurysm of the aorta.

Ross, Clarence Wesley ⊕ Captain, U. S. Navy, retired, San Diego, Calif.; University of Oregon Medical School, Portland, 1912; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; entered the U. S. Navy June 26, 1915; retired Feb. 1, 1948; died Oct. 2, aged 67.

Rudd, James Colegate ⊕ Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1931; specialist certified by the American Board of Radiology; served overseas during World War II; affiliated with the Veterans Administration Hospital, where he died Sept. 18, aged 46, of melanoma.

Salyer, Kelson N., Hazard, Ky.; Loyola University School of Medicine, Chicago, 1919; also a lawyer; served during World War I; at one time representative in the state legislature and county judge; one of the organizers of the Citizens State Bank and in recent years served as its president and chairman of the board; died Sept. 9, aged 63, of a cerebral accident.

Sevier, Ernest ⊕ Sacramento, Calif.; University of California Medical School, San Francisco, 1927; affiliated with Sutter and Mercy hospitals; died Sept. 5, aged 58, of coronary thrombosis.

Shaw, Harry William, New Lexington, Ohio; Starling Medical College, Columbus, 1898; served during World War I; on the staffs of the Bethesda and Good Samaritan hospitals in Zanesville; died Sept. 15, aged 79, of coronary occlusion.

Sidell, Samuel ⊕ Boston; Tufts College Medical School, Boston, 1926; member of the New England Obstetrical and Gynecological Society; chief of the obstetrics department, Allerton Hospital, and senior obstetrician, Booth Memorial Hospital in Brookline, Mass.; on the associate staff, Beth Israel Hospital, Boston; died in New York City Sept. 12, aged 51, of coronary thrombosis.

Sloan, Charles Elmer, North Little Rock, Ark.; Kansas City College of Medicine and Surgery, Kansas City, Mo., 1917; died Sept. 17, aged 74, of pulmonary occlusion and myocardial infarction.

Smith, Loran Eugene, Danville, Calif.; University of Illinois College of Medicine, Chicago, 1950; interned at Santa Clara County Hospital in San Jose, where he served a residency; killed Aug. 23, aged 33, in an automobile accident.

Stansberry, Charles Lee ⊕ Oneonta, Ala.; Medical Department of Grant University, Chattanooga, Tenn., 1899; died in Blount Memorial Hospital in Maryville, Sept. 18, aged 85, of pneumonia.

Stout, Gurn Thompson ⊕ Los Angeles; University of Nebraska College of Medicine, Omaha, 1926; drowned off Boat Canyon in Laguna Beach Sept. 13, aged 54, while diving.

FOREIGN LETTERS

BELGIUM

Professor René Sand.—Dr. René Sand died recently. He originally worked in the field of pathological anatomy and later became interested in the study of industrial accidents, and then in occupational medicine and pathology. After World War I he became secretary of the International League of Red Cross Societies, and professor of social medicine at the University of Brussels. He was the author of "Toward Social Medicine," and was founder and first president of the Belgian Society of International Medical Law.

Allergy.—At a meeting of the Belgian Society of Gastroenterology in May Mr. Froehlich emphasized the difficulties in the diagnosis of digestive allergies. The lesions range from simple edema to the acute necrosis associated with the Arthus phenomenon, and are characterized by changes in the capillary endothelium, venous thromboses, and pericapillary hemorrhages. The affected region is infiltrated by neutrophils and eosinophils. Monocytes, histiocytes, and plasmocytes are also found. Although these lesions may evolve toward granulomas with a tuberculoid or rheumatoid structure, they are not pathognomonic of allergy but only constitute a basis for assuming the allergic nature of the process. The phenomena of Reilly and the general adaptation phenomenon of Selye can bring about similar alterations. Other criteria of digestive allergies are contractions of the blood vessels, secretion of mucus, and favorable response to antihistaminics and oxygenated steroids. The most certain criterion is the isolation of a specific antibody, which is easy to detect if it exists in an appreciable quantity in the serum. The use of precipitins and of cutaneous or intradermal reactions may provide interesting responses, but in patients with digestive allergies the nature of the antigen usually remains unknown, because the sensitivity may be solely histological. Anaphylactic shock is then delayed, and these methods are of little or no help. These patients must be subjected to repeated examinations. Furthermore, the radiological and endoscopic alterations are not characteristic of the causal process. Why some patients have allergic symptoms when most persons under the same conditions do not is a major problem. The psychic state of the patient certainly plays a preponderant part. Gutmann's idea that as the result of certain modifications the organ becomes the organ of shock must be kept in mind. Needle biopsy of the liver, if better studied and especially if more precise, could help to demonstrate edema. The therapy is not specific; antihistaminics and corticotropin have been used with some success, and elimination regimens have their ardent defenders. We were used to the idea of transience in allergies, but—and this has been recently discovered—there is a slowly evolving type of allergy that causes permanent histological changes. This process may play a part in the pathogenesis of ulcers, regional ileitis, and ulcerative colitis.

Treatment Center for Poliomyelitis.—The treatment facilities dealing with poliomyelitis should be equipped to treat patients in the acute stage, the convalescent stage, and the orthopedic or definitive surgical stage. This requires years of treatment. For this reason a treatment center where a patient with poliomyelitis can be treated from the very first day of his illness until the definite healing has occurred has been set up at the College of Medicine in Gant.

Streptomycin and Tuberculous Meningitis.—At the 14th Congress of Pediatricians of the French Language, in May, 1953, Dr. Nameche of Brusssels presented a report based on the first two years' results of Belgian experience with streptomycin in the treatment of tuberculous meningitis. He reached the following conclusions: 1. The coexistence of a state of granulation has no influence on the general prognosis of tuberculous meningitis. 2. The unfavorable effect of a late diagnosis is evident in the mortality rate in the first month. 3. The mortality curve for tuberculous meningitis according to the age of the patients is parallel to the same curve for all forms of tuberculosis (this mortality is very high for infants and at puberty). 4. Strict and prolonged adherence to the therapeutic regimen has reduced the general mortality and has decreased the number of relapses. 5. These rigorous treatments have two drawbacks: long duration and risk of deafness. 6. Although treatments with streptomycin given simultaneously by intramuscular and intraspinal injections seem to necessitate strict and prolonged administration during the first three months, it is likely that these treatments when combined with other antituberculous agents can be made less rigorous during the later months without increasing the risks to the patients. The Belgian experience, however, is not yet sufficient to determine the efficacy of the addition of isoniazid to streptomycin in the treatment of this disease.

Medical Examination of Students.—A royal decree has recently been issued making medical examination for the exclusion of contagious diseases compulsory prior to registration in state universities as well as in the school and institutes connected with them, at the state school of veterinary medicine, and in the state agricultural institutes. Students whose registration has been refused on medical grounds may demand a second examination when there is reason to believe that they are free of contagious disease.

CHILE

Acute Abdominal Conditions.—In the April number of the quarterly of Viña del Mar Hospital, there was an article on acute abdominal conditions seen in the emergency service of that hospital during 1951. Among 15,900 patients observed at the emergency station, 2,910 (18%) had acute abdominal conditions. These included 947 patients with biliary colic, 461 with gastroenteritis, 394 with acute gastritis, 243 with acute appendicitis, 218 with chronic cholecystitis, 135 with colitis and enterocolitis, 91 with adnexitis and salpingitis, 49 with renal colic, 43 with gastroduodenal ulcers, 32 with acute cholecystitis, 28 with ectopic pregnancy, 22 with hernias, and 13 with pancreatitis. The rest included entities such as hepatitis, tuberculous peritonitis, pelviperitonitis, and gastric carcinoma. The authors outlined the manner in which these patients must be examined. The history of these patients at times is difficult to obtain, because they are in a state of shock or have pain, and must be orientated toward three main symptoms, pain, vomiting, and constipation or diarrhea. Regarding pain, its radiation, intensity, type, evolution, point of origin, and coexistence with other signs or symptoms are important. Continuous pain may be acute or chronic. Acute pain, if followed by shock, suggests rupture, perforation, or torsion. In the absence of shock, it may accompany appendicitis, acute cholecystitis, pyelitis, and adnexitis. Continuous or intermittent chronic pain suggests peptic ulcer or chronic cholecystitis. Colicky pain is usually due to mechanical obstruction of the gastrointestinal tract, but may be reflex in patients with tumors or mesenteric cysts. A third type of pain is that associated with tabes dorsalis, syphylitic meningomyelitis, and tuberculous pachymeningitis.

Vomiting is one of the commonest signs in patients with acute abdominal conditions. It is most intense in patients with intestinal obstruction, especially if there is strangulation of the small intestine. It appears early in patients with appendicitis and is rather persistent in patients with pancreatitis. It is less frequent than thought in patients with cholecystitis. The laboratory and x-ray department are of great help in arriving at a correct diagnosis.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Bulletin of Chilean Society of Cardiology.—The board of directors of the Chilean Society of Cardiology decided on April 25 to publish a bulletin that will be the official organ of the society and will appear three times a year. The first issue appeared recently and contained an article on normal and abnormal ballistocardiograms by Prof. Rojas Villegas and others. The authors concluded that Dock's photoelectric method produces satisfactory tracings with a constancy that permits the comparison of successive tracings. The size of the recorded waves vary greatly in normal persons but their amplitudes decreases in those of persons over 40 years of age. The normal tracings present morphological alterations of the waves in a very low percentage. Finding these alterations in more than 20% of the tracings indicates an abnormal condition. The tracings of 174 patients (44 with valvulopathies, 40 with arteriosclerosis, 40 with angina pectoris, 30 with myocardial infarction, and 20 with hypertension) were studied. They were compared with those of 100 normal persons. In order to evaluate the tracings objectively, the authors proposed a point system giving to the various patterns a definite number of points. Although this system is arbitrary, it gave them a scale with which to compare various tracings. Most of those from subjects considered normal had less than 50 points, whereas those from the abnormal subjects had more than 50 points on this scale. The tracings of the patients with valvulopathies, however, fell within the normal range, but no significant difference was observed between the scale ratings of ballistocardiograms from patients with arteriosclerosis, angina pectoris, and hypertension. Those of patients with myocardial infarction were significantly different from those of patients with hypertension and arteriosclerosis but not from those of patients with angina pectoris. The authors concluded that the ballistocardiograph lacks specificity and at present is not of great value in the diagnosis of coronary insufficiency.

An electrocardiographic study of 30 normal pregnant women was reported by Dr. A. Illanes and co-workers. Of these, 24 showed electrocardiographic changes of the P-waves, Q-waves, and T-waves, the electrical position of the heart, the direction of the electrical axis, and the ventricular gradient in the course of pregnancy. The auricular complex showed changes in the last three months of pregnancy, becoming negative in 13 and diphasic in 6. Markedly negative Q_3-waves, which had no pathological meaning and which were due to changes in the electrical potential of the heart were observed in six patients. The T-waves became negative in 14 because of changes in the electrical position of the heart. In the precordial leads the T-waves became negative in V_1 in 22 patients and in a smaller proportion in the other leads (V_2 in 4, V_3 in 1, and V_4 in 1). In 14 patients, the heart rotated counterclockwise on its anteroposterior axis in the course of the pregnancy. The ventricular gradient moved to the left an average of 7 degrees (range 3 degrees to 22 degrees).

Acute Hepatitis in Children.—In the May issue of the *Revista Chilena de Pediatria,* Dr. H. Niemeyer and others, reported 65 cases of acute hepatitis in children ranging in age from six months to 11 years, with 60% of the children under 4 years of age. Slightly less than half of the children had a history of contact with patients suffering from viral hepatitis or of blood transfusions made during a maximal incubation period. A preicteric period of about three days and characterized by anorexia, lassitude, fever, mucous discharges from the respiratory tract, or gastrointestinal disorders, was observed in 61 patients. The first symptom of the icteric stage may be bile-stained urine, acholic stools, or jaundice of the skin or mucosa. In 36, the jaundice was of medium intensity, but in 22 it was intense. General symptoms may disappear rapidly in this stage of the disease. Hepatomegaly was present in all the patients, but splenomegaly was present in only 13. In the posticteric stage, hepatomegaly persisted and resolved very slowly. In a group of 20 of these patients, the average total serum bilirubin was between 20 and 55 mg. per 100 cc. Cephalin-cholesterol flocculation, colloidal gold, scarlet red, and thymol turbidity tests were consistently abnormal in most of the patients with a gradual improvement leading to normality in from 20 to 180 days. The positive flocculation tests and hepatomegaly were the last abnormal findings to disappear.

Patent Urachus.—In the *Revista Chilena de Pediatria* for May, Dr. Ines Ulloa Acuna reported on four patients (three girls and one boy) with patent urachus. Two of the girls also had vesicoumbilical fistulas and were operated on during their second month of life. Both made uneventful recoveries. The other two patients had suppurating cysts of the urachus and were seen during their second year of life 15 days after the onset of the acute symptoms. In both patients, the cysts were evacuated, and, after the infection was controlled with antibiotics, they were removed and healing was prompt.

DENMARK

Falling Tuberculosis Death Rate.—On Sept. 5, at the annual meeting of the Danish National Association Against Tuberculosis, Dr. J. Gravesen presented some remarkable figures dealing with tuberculosis. Between 1948 and 1952 the tuberculosis death rate has been more than halved, with 1,034 deaths from all forms of tuberculosis, or 25 per 100,000 persons, in 1948, as compared with 471 such deaths, or 11 per 100,000, in 1952. Each of the years between 1948 and 1952 showed a steady fall of the tuberculosis death rate. Thirty years ago tuberculous meningitis was responsible for about 13 deaths per 100,000 every year, whereas in 1952 this figure was reduced to 0.3. In 1935 deaths from tuberculosis among children from birth to 14 years old numbered 235, or 25 per 100,000. In 1948 there were only 68 such deaths, or 6 per 100,000. In 1952 the deaths at this age numbered only 10, or 0.9 per 100,000. In the same year in Copenhagen alone there were no deaths from tuberculosis among patients under the age of 14. In 1935 there were 29 tuberculosis deaths per 100,000 children in Copenhagen, and in 1948 this ratio was reduced to 8 per 100,000. The tuberculosis morbidity rate presents a very different picture. The figures for 1952 are not yet available, but those for 1951 show that in this year alone 2,412 new cases of pulmonary tuberculosis were reported, a rate of 56 per 100,000 persons. The corresponding rate in 1950 was 59 per 100,000. The records of the Danish Public Health Service show that there are still about 15,700 persons suffering from pulmonary tuberculosis in the country, and, if the other forms of tuberculosis are taken into account, the total of still-living tuberculosis patients can be brought up to more than 16,500. These figures and their counterparts in the other Scandinavian countries show that though persons have almost ceased to die of tuberculosis, they continue to suffer badly from it.

Penicillin Prophylaxis of Streptococcic Infections.—In the wing of the Refsnaes Coast Hospital for children not suffering from tuberculosis, Dr. Sven Helbo has undertaken a comparative study of the efficacy of penicillin given by mouth as a preventive of streptococcic infections. He divided the children into two equal groups based on odd and even admission numbers. Between January and May, 1951, each child in one group was given daily two tablets containing 100,000 units of penicillin. The children in the control group were given placebos, and neither the children nor the staff of the hospital knew which tablets were which. The 70 children in each group were kept under close supervision with the routine taking of throat swabs, the erythrocyte sedimentation rate, and the antistreptolysin titer. At the outset 9 children receiving penicillin tablets and 10 children receiving the placebos had streptococci in the throat. All the fortnightly swabs taken from the penicillin-treated group yielded negative cultures, whereas 21 of the controls yielded positive results. There were two cases of tonsillitis and one of otitis media among the controls and no such streptococcic infections in the penicillin-treated group.

A new series of tests was carried out late in 1951 and early in 1952 on 98 children who were given penicillin by mouth and 108 controls who received placebos. At the outset 18 of the penicillin-treated group and 24 of the controls had streptococci in the throat. The swabs taken fortnightly showed no infection of the penicillin-treated group and 39 carriers in the control group. In this group there were 20 definite cases of streptococcic infection as indicated by clinical findings, positive swabs, and a secondary rise of the antistreptolysin titer. There were no such cases in the penicillin-treated group, whose members spent a total of 6,542 days in the hospital without streptococcic infection, whereas the members of the control group spent 7,173 days in the hospital with 111 days representing streptococcic infections. Other infections, represented by rhinopharyngitis and chickenpox, also behaved differently in the two groups, with the control showing twice as great a morbidity as the penicillin-treated group.

Discussing these findings, Helbo concluded that prophylactic treatment with penicillin is effective both with regard to the carrier state and actual disease due to streptococci. The risk of producing penicillin-resistant strains of streptococci seems to be small, and in none of his patients did he observe reactions indicative of penicillin allergy. He admitted that such prolonged penicillin treatment is likely to induce a black deposit on the teeth, and that a natural immunity to streptococcic infections in the hospital may not develop in the children thus treated.

The Ideal Medical Partnership.—Dr. J. Riising, who has grown old in helping his colleagues settle partnership quarrels, has recently told the readers of *Ugeskrift for Laeger*, the organ of the Danish Medical Association, what he thinks is the ideal medical partnership and what can best be done to avoid the tragedies of partnerships dissolved in mutual bitterness. Since human nature is much the same the world over. Riising's experiences also may be helpful to physicians who are not Danes. In the first place the ages of two partners may determine success or failure, and the ideal would be a gap of about 20 years between them. If partners are of the same age, they may have the same set of friends and the one may find it hard to remain on duty while the other dines with friends who have invited both of them. Besides, when the wives and children are of the same age, gossiping and quarreling are apt to be comparatively common among them, whereas an elderly partner and his wife can adopt a parental attitude to the family of the younger partner. The elderly doctor must begin to look for a partner before his own practice begins to wane. Statistics compiled by Danish health insurance societies show that a practice seldom increases after the doctor has passed 50. This happens because of the deaths and changes of address of his patients, not because they have deserted him. Riising has found that there is no standard contract suitable for all. Each contract must reflect the special requirements of the two parties, but it is a good general rule to provide in a contract for a year's trial of the ability of the two to work well together. Every contract should also include a dissolution paragraph defining exactly the conditions under which two doctors shall part. Such a paragraph may have a usefully inhibitive effect on an irritated partner who, on reading it, is reminded how costly it will be for him to take the first step. In Riising's opinion, such a dissolution paragraph should carry a greater penalty for the man who wants to break away. As a rule, this paragraph should assure the departure of one of the partners from the area in which they have practiced, for much trouble will arise from further proximity of ex-partners. The paragraph may be so worded that the partner who takes the initiative in dissolving a partnership must also leave the neighborhood, or it may be the younger partner who must do so. In any case, whether a partnership is successful or disastrous, Riising agrees with Ibsen in giving woman the credit for either.

MEXICO

Anatomic and Radiological Studies of Thoracic Lymphatics.—In recent years, Dr. Alejandro Celis of Mexico City and his collaborators have studied the lymphatics of the thorax in cadavers of normal subjects and of those with pulmonary disease. Some of the findings in 50 human cadavers were described in the *Acta radiologica* (38:461-470 [Dec.] 1952). They removed the ninth rib from one group of bodies. The aorta was then dissected and pulled forward, by which approach they were able to identify the thoracic duct in most cases. In others they injected a dye and followed the dissection upwards into the neck as far as the termination of the duct. In another group the thoracic duct was injected with dye and carefully dissected from the diaphragm to the upper part of the thorax, and its course, relations, ramifications, and branches studied. In most cases they found a single trunk of variable diameter, tortuous and constricted at intervals, ascending through the posterior mediastinum behind the esophagus between the aorta and azygos veins. In two cases they observed that the thoracic duct divided into two vessels of about the same size, which reunited at about the level of the fourth thoracic vertebra. In three they found several trunks opening into the thoracic duct at the level of the aortic hiatus of the diaphragm. In two cases they encountered a branch communicating with a plexus of lymphatics around the aorta at about the level of the seventh and of the eighth thoracic vertebras respectively. In two cases a branch was found connected with a small plexus of lymphatic capillaries that surrounded both the aorta and the esophagus, and in the last two cases they were able to identify several branches that were traced back to a group of lymph nodes at the level of the pulmonary hilus. In some of these cadavers the injected dye filled certain branches and stained several lymph nodes. In another group the left subclavian, left internal jugular, and left innominate veins were tied, and, after removal of the eighth rib, a left thoracotomy was performed. The thoracic duct was dissected for 10 cm. just above the aortic hiatus of the diaphragm and a needle connected to a catheter introduced into the duct. The opening into the thoracic cavity was then sutured and the body taken to the roentgen department, where a radiopaque substance was injected under fluoroscopic observation and films obtained.

National Campaign Against Typhus.—The morbidity rate from epidemic typhus in Mexico has oscillated between 4.8 and 14.4 per 100,000 in the years from 1939 to 1951. Dr. Carlos Ortiz-Mariotte, chief of the National Campaign Against Typhus, reported in the March, 1953, issue of the *Boletín de la Oficina sanitaria panamericana* (34:236-244, 1953) that, although Mexico's Public Health Service applied chlorophenothane (DDT) powder to infested persons and contacts as a typhus control measure as early as 1944, insufficient and deficient coverage allowed outbreaks to continue throughout the country. In 1951, therefore, a nation-wide campaign was initiated to eradicate the typhus vector, the body louse.

Chlorophenothane powder was used alternately with other insecticide powders with a residual effect to prevent development of resistant strains of the vector. Experiments showed that laundry soap containing 5% chlorophenothane is very effective in killing the typhus vector and that soap containing 3.5% is adequate. Soap containing 2% chlorophenothane is now being studied. It was also found that after one year the impregnated soap retains over 75% of its insecticidal potency. Efforts are being made to interest large soap manufacturers in producing and marketing this type of soap, to be sold at cost. For head delousing, petroleum jelly (Vaseline) containing 2% chlorophenothane, which is more acceptable than kerosene, chlorophenothane powder, or shaving the scalp, was produced.

The selection of communities for louse surveys is based on social, economic, and epidemiological factors known to be compatible with a high incidence of lice. Mass treatment is administered in communities that show an index higher than 30%; selective treatment by blocks is applied in those having an index of from 10 to 30%, and selective treatment by families is used in communities with an index lower than 10%. All clothing and other articles that come into contact with the body are treated with chlorophenothane powder.

The original infestation rate was 3.1 times the rate after treatment of clothes with chlorophenothane powder and 4.5 times that after use of chlorophenothane soap. The petroleum jelly preparation is not only 100% effective for hair delousing but its residual effect kills the larvae. While treatments are being administered, the population is instructed on the objectives of the campaign, the effect of chlorophenothane powder, the cooperation that is expected from each family, and how to obtain and use the insecticides.

CORRESPONDENCE

CHRISTIAN MEDICAL COUNCIL FOR OVERSEAS WORK

To the Editor:—Readers of THE JOURNAL, who follow the progress of international relations and medical programs of an international nature, may be interested to know about the Christian Medical Council for Overseas Work and its varied activities. This council, which was created in 1938, is the central medical organization that serves primarily the interests of 50 Protestant church foreign mission boards that maintain organized medical work abroad—about 800 hospitals, 15 tuberculosis sanatoriums, 150 schools of nursing, and approximately 2,000 independent dispensaries, as well as 4 medical colleges and a union medical training institute in the Congo. These societies partially support this office as a center of information and advice for their far-flung medical enterprise.

The council's activities include the recruiting of personnel—general physicians and surgeons, specialists, dentists, nurses, hospital administrators, technicians, medical social workers, and health educators; the counseling of candidates in these fields regarding preparation for service overseas; formulating programs of graduate study and clinical experience for a rapidly increasing number of persons coming to the United States; arranging itineraries and short-term service appointments abroad for specialists from the states; receiving gifts of supplies, equipment, books, and journals for overseas use; and instructing nonmedical missionaries in the principles of hygiene, community health measures, and simple medical services. The four medical schools, one each in Seoul, Vellore, Miraj, and Ludhiana, one union medical training institute in the Congo, and a projected medical college in the Philippines are all important concerns of the council, particularly with respect to staff. If there are any who are interested in helping this organization carry out its functions more effectively or who wish to participate personally in the work of one of the overseas institutions, I shall be glad to hear from them.

DOUGLAS N. FORMAN, M.D.
Secretary, Christian Medical Council

ANEURYSM OF CHOLECYSTIC ARTERY

To the Editor:—A recent article on the management of gastrointestinal hemorrhage of undetermined origin (Bockus, H. L., and others: *J. A. M. A.* **152:**1228 [July 25] 1953) reminds me of what I believe to be a unique case. The patient died in 1939, and I performed the autopsy. A woman in her late forties was admitted to a general hospital. She had been under treatment for syphilis by her private physician for several months. About one month before admission to the hospital, she passed a large, but unknown, amount of bright red blood by rectum. Hospitalization was urged by her physician but refused. Hemorrhage occurred again two or three times. The woman became very weak and finally consented to go to the hospital. On admission she was very weak and pale and had an erythrocyte count of less than 2 million, with a correspondingly low hemoglobin level. The blood pressure was quite low. Sigmoidoscopy and a thorough roentgenologic survey of the gastrointestinal tract were uninformative. Physical examination revealed nothing but hypotension.

During the first week in the hospital, there was no frank bleeding. At the end of the first week, a transfusion of 500 cc. of whole blood was administered. Within two hours after the transfusion, there was a severe hemorrhage by rectum, and after the hemorrhage the red blood cell count and blood pressure fell below what they had been on admission. The transfusion was repeated three or four times during the next few weeks. Each time severe hemorrhage followed the transfusion within two hours. Death followed a few hours after the last transfusion.

Autopsy was performed about two hours after death. On opening the body, it was seen that the intestinal tract contained a large amount of fresh red blood from pylorus to rectum. The liver was removed and laid aside for later attention. The gastrointestinal tract was removed intact from upper esophagus to rectum, was carefully opened and rinsed, and was minutely inspected throughout. No fecal material was identifiable; it probably had been washed out by the hemorrhage. Absolutely no source of bleeding could be found in the intestinal tract. No evidence of blood was found above the pylorus. I then glanced at the liver and saw a large drop of blood hanging from the end of the common duct. Careful dissection along the common and cystic ducts led to the discovery of a saccular aneurysm of the cholecystic artery, about 8 mm. in size. This had ruptured into the cystic duct just below the gallbladder. This was obviously the source of the hemorrhage. It seems reasonable to believe that, as the blood pressure was reduced by hemorrhage, the arterioductal fistula was closed by thrombosis and remained closed until the blood pressure was again raised by transfusion. This phenomenon was repeated until—apparently—the blood was unable to clot, and the fatal hemorrhage ensued.

In the light of the article by Bockus and his associates, it now seems that this woman's life might have been saved. By gently milking the duodenum downward from the pylorus, the level of the hemorrhage could probably have been located at the region of the ampulla of Vater. I have no doubt that on opening the duodenum at this level, very active hemorrhage from the common duct would have been seen if a transfusion had been given just before the abdomen was opened. Careful dissection along the duct would then have revealed the aneurysm (during life it might have been palpated), and the source of hemorrhage could have been removed. Further transfusion would then have been effective.

RECTAL PAIN

To the Editor:—We should like to call attention to a cause of rectal pain that, to the best of our knowledge, has not been mentioned in the literature. This infrequent but definite clinical entity is hemorrhage into a hypertrophied anal papilla. A normal anal papilla becomes hypertrophied because of infection and trauma. Infection may extend from adjacent crypts of Morgagni, either associated with or independent of a true proctitis. Infection of the wounds after anorectal surgery commonly produces marked and rapid swelling and hypertrophy of a papilla that was so small that it was overlooked at the time of surgery. We always excise or destroy all anal papillae found at anorectal operations with a cautery. Trauma occurs at stool when the papillae, which normally project upward, are either everted or dragged down with a hemorrhoid; thus, trauma to an already inflamed and hypertrophied papilla can easily produce a hemorrhage into the papilla with a typical chain of events.

There is usually a history of sudden onset of a severe pain "up in the rectum" that appeared soon after defecation. There may or may not be protrusion or blood from associated hemorrhoids or fissure. The pain is a severe ache-like pressure and bearing down feeling in the rectum proper; it in no way resembles the burning discomfort of a fissure. Little or no relief is obtained from heat or analgesic ointments applied locally. Relief usually requires opiates or surgical intervention. Diagnosis is easy and can usually be made on examination by insertion of a finger. The enlarged papilla can be felt as a smooth, tense, exquisitely tender swelling. Confirmation is made after insertion of a beveled anoscope when the papilla can be seen arising from the dentate line and having a characteristic blue discoloration from the contained blood. Confusion in diagnosis can arise only from a hemorrhage into an internal hemorrhoid. The symptoms are quite similar, but the latter is several times larger, has no free end, and is covered with rectal mucous membrane. In our experience, hemorrhage into an internal hemorrhoid, while mentioned in the literature, is less common than hemorrhage into a hypertrophied anal papilla. Treatment is surgical and consists of incision or excision with the patient under local anesthetic as an office procedure, or excision together with correction of associated abnormalities as a hospital procedure. Occasionally the papilla will rupture and result in complete relief of symptoms. Inspection then shows a small clot protruding from the rupture, similar in appearance to an external thrombotic hemorrhoid that has ruptured. Hemorrhage into an hypertrophied anal papilla should be suspected when the patient complains of symptoms as outlined.

BLOOD PRESSURE STUDY

To the Editor:—My associates and I are engaged in a study of the blood pressure in persons aged 65 and over. The study is sponsored by the New York Heart Association. Early in September we mailed questionnaires to 17,000 physicians throughout the country. Each physician received a letter of instruction for filling out the questionnaire. It was suggested that he supply blood pressure and other data on six cases, if possible. Thus far the number of responses has been disappointingly small. Although we realize that a relatively short time has elapsed since the questionnaires were sent out, we are afraid that many physicians may not appreciate the value of this study and the fact that it will fail unless they give their full cooperation.

In order to bring these facts to the attention of the medical profession, we would appreciate it if you could mention the project, and urge the support of physicians. Filling out the questionnaires does not require much time, and many physicians will, we hope, take the trouble to do so if they understand the importance of their cooperation. Questionnaires have been sent to only about 1 in 15 physicians. Those who have received questionnaires are urged to complete them. An additional supply of cards is available at Blood Pressure Study, 11 E. 100th St., New York 29. Others who are interested and wish to participate may do so by mailing a postcard to the same address.

REPRINTS ON STRESS

To the Editor:—In 1950, our institute initiated the publication of a series of reference volumes entitled "Annual Reports on Stress" (Montreal, Acta Medical Publishers) in which the current world literature is surveyed every year. Up to now, we have compiled the pertinent literature partly from medical periodicals, monographs, and abstracts and partly from reprints sent to us by authors. Of all these, reprints proved to be the best source of data that we felt deserved prompt attention in our annual reports. To insure prompt inclusion of publications in the annual reports, investigators interested in stress research are requested to send us their reprints as soon as they are available.

TREADMILLS

To the Editor:—I was interested by the article by Simon and Wright in The Journal, Sept. 12, 1953, page 98, describing a motorized treadmill for quantitating intermittent claudication. I developed this apparatus 10 years ago in the Peripheral Vascular Disease Clinic of the Maimonides Hospital, and it has been in use there since. While the treadmill has long been used in metabolic laboratories for the study of energy exchange, the development of a motorized treatmill in which the rate of walking could be controlled and used for determining walking capacity and quantitating intermittent claudication was new and original with my invention. A description of the apparatus and its use in the evaluation of peripheral arterial impairment is included in the second edition of "Peripheral Vascular Diseases: Diagnosis and Treatment" (Collens, W. S., and Wilensky, N. D.: Springfield, Ill., Charles C Thomas, 1953).

It was at Dr. Wright's request that I permitted one of his resident physicians to visit my clinic to see the operation of this equipment and, with my permission, to duplicate this technique at the New York Hospital Peripheral Vascular Disease Clinic.

W. S. Collens, M.D.
123 8th Ave.
Brooklyn, N. Y.

To the Editor:—In reply to the letter by Dr. William S. Collens, we are very glad to extend to Dr. Collens, and to all others who have contributed to the use of the treadmill principle in the measurement of physiological response, due credit for any advances that may have led to the development of the equipment described in our article in The Journal, Sept. 12, 1953.

Dr. Collens did permit Dr. Simon to see his equipment. In order to conserve space, however, we did not review the history of the treadmill as it is presently applied. Actually, the equipment described in our paper differed in some details from that of Dr. Collens. It was largely an outgrowth of the type of treadmill used for many years in the laboratory of Dr. Eugene DuBois of the Cornell University Medical College. Our purpose in describing the equipment in some detail was simply to permit duplication by others who might wish to repeat our studies or to utilize the same technique in the evaluation of other substances that may be suggested for the treatment of intermittent claudication. This we consider to be sound practice in the presentation of any experimental data.

AMERICAN IN JENA

To the Editor:—On my recent visit to Europe, a German professor of medicine told me the following story. In 1945 he was in Jena when American troops entered that city. Martial law was declared, and the citizens were forbidden to leave their homes. With fixed bayonets, American soldiers patrolled the city. This professor too cowered in his home, shivering and quivering. Suddenly there was a violent knock on his door. He thought his last hour had come. Trembling and covered with cold sweat, he opened the door. There, in full regalia, stood an American medical officer. The officer pulled a book from his pocket and asked sternly: "Are you Professor . . .?" "Ye-e-s-s," stuttered the frightened professor. "Did you write this book?" demanded the officer. The professor nodded a weak yes. "Then, please autograph it for me." This done, the officer snapped, "Thank you very much," came to attention, saluted, turned on his heel, and marched off.

COUNCIL ON MEDICAL SERVICE

CONFERENCE ON PHYSICIANS PLACEMENT SERVICE ACTIVITIES

Following are the summary and conclusions of the Council's second regional conference on physicians placement service activities prepared by Rowland B. Kennedy, Executive Secretary of the Mississippi State Medical Association, who acted as conference summarizer.—Ed.

The second regional Conference on Physicians Placement Service Activities was conducted in Asheville, N. C., by the Committee on Extension of Hospitals and Other Facilities,[1] Council on Medical Service, on Sept. 19, 1953, at the Battery Park Hotel. Ralph A. Johnson, M.D., Detroit, chairman of the sponsoring committee, presided. The conference was opened at 9:30 a. m. with 25 participants present, among whom were constituent society officers and committeemen, constituent society executives, representatives of medical schools, staff members of the American Medical Association, and a health council executive. States represented were Pennsylvania, Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Mississippi, and Alabama.

The chair oriented the conference on the background of placement service activity, pointing out the function of the American Medical Association in its role as a coordinating agency. Essentially, placement service is concerned with effecting optimum distribution of physicians throughout areas of need. The mechanics of the services are extremely direct, working most effectively from state level with the benefit of active assistance from the A. M. A. headquarters office.

Each participating state in reporting to the conference demonstrated a positive approach to the placement problem, but the degrees of emphasis upon the approaches varied widely. Factors influencing these degrees of emphasis included present supply of physicians, eccentricity of state law in medical licensure, attitudes held in constituent societies, economic and other indigenous considerations. Views expressed, however at variance in plan and detail, all sought the common solution of effective physician distribution throughout areas of need. No reporting state conveyed an impression of having regarded the problem passively.

VIRGINIA'S AGGRESSIVE APPROACH

Physicians placement service activity in Virginia is a function of the Virginia Council on Health and Medical Care. This council is comprised of some 55 member organizations among which is the Medical Society of Virginia; it is supported by the member groups, and a central office for this independent activity is maintained by an executive staff. The placement program of the council is a vigorous undertaking to supply physicians to communities with insufficient medical services. To accomplish this mission, the council makes use of a wide area of contacts through communities, organizations, physicians, county medical societies, hospital training programs, and medical schools. The program ultimately contemplates the effective placement of all graduates of Virginia medical schools and now works closely with students in the third and fourth years. The present service seeks placements (1) for an area of need where there is no physician, (2) for replacing physicians entering military service, (3) for needed specialists, (4) for associates and assistants, and (5) for replacing physicians lost through removal and death.

It is a policy of the council that its assistance in obtaining physicians must be sought by communities. Through the medium of field visits, questionnaires, and surveys aimed at determining the degree of need, the council achieves a dual purpose. First, a calculated attempt is made to educate the community to its responsibility in obtaining the physician with council assistance, and, secondly, overconcentration of medical service is fortunately avoided. While the physician is being obtained, the community is revisited to maintain interest in the enterprise. Final placement, wisely enough, depends upon arrangements and agreements arrived at by the community and the physician. A final service is furnished toward making the placement permanent by continuing the relationship initially established between the community and the physician placed. The council coordinates its activities closely with the Medical Society of Virginia and the American Medical Association.

INDIVIDUAL STATE PLACEMENT PROBLEMS

Each reporting state listed problems encountered in making a placement service effective. Among these, two reports appeared to sum up problems most nearly common to all. It was found that there was difficulty in evaluating accurately the extent of need for placement of a physician. Apparently, the best solution to this problem is use of the A. M. A.-prepared priority rating plan. Still another problem is found in the supply of physicians available to states to satisfy demonstrated needs. This problem does not presuppose a shortage of physicians nationally but rather tends to point up certain local areas of maldistribution wrought by legal peculiarities, below-average economic levels, population distribution, and facilities available. The lack of hospital facilities, more recently a problem with which nearly all areas can better cope because of the Hill-Burton program, still influences the unsatisfied need in some localities. Areas with low, unstable economic levels experience difficulty in procurement of physicians, while the lack of social advantage also poses problems.

The combined thinking of the conference for approaching solutions to the common problems of procurement in placement activity centered about establishing community responsibility for providing medical service for which there is demonstrated need. Reasonable assurances of income, adequate clinical facilities, desirable environment for his family, all tend to encourage a physician to accept a location opportunity.

MEDICAL EDUCATION'S ROLE IN PLACEMENT

Among the members of the conference were representatives of three medical schools who discussed with the conferees certain didactic aspects of medical education that tend either to influence or dissuade rural practice. There was not a pronounced tendency among the schools represented to produce specialists but rather graduates who are adequately prepared to undertake general practice or to pursue further training. The tendency for medical graduates to return to native localities, the weaknesses inherent in rural secondary education, and the superior opportunity for training and practice in the urban areas appeared a chief reason for difficulties in rural procurement. Not all conferees found this problem without resolution, and nearly all constituent societies reported active rural health programs.

A. M. A. PLACEMENT SERVICE

Physicians placement service activities of the American Medical Association are conducted by the Council on Medical Service through its staff in the Chicago headquarters office. Working files of requests, of physicians available for specified areas, and of location lists within states, follow-up files, correspondence, and liaison activity constitutes much of the task of maintaining this central and necessary coordination.

During the summer of 1953, Mr. Jack Riner, a medical student at Northwestern University, temporarily in the employment of the council, visited headquarters' offices of six constituent societies and examined state level placement programs. His report was absorbing and revealing, bringing out with clarity a majority of the problems encountered as well as explanations of techniques successfully developed.

The criteria developed during 1952 concerning the priority rating of communities in search of a physician was explained. This priority rating plan, in which numerical values are used in grading need and facilities, is being successfully applied. The plan offers what may be the best basic approach for objectively evaluating requests for physician placement.

Based largely on the findings of the Virginia approach, placement service activity appears as a vital adjunct to medical public relations. It obviously aids the economy of any given area in assuring medical care. Social and economic advantages accruing to rural life are seen from adequate medical service brought about through this program. Finally, it is meeting a recognized, existing need in effecting a better distribution of physicians as a positive countermeasure against the force of socialization. The chair reemphasized the role of the A. M. A. placement service activity as a catalyst or coordinating agency in what is primarily a state responsibility

---

[1] The Committee members are Drs. Ralph A. Johnson, Chairman, Detroit; Elmer Hess, Erie, Pa.; Walter E. Vest, Huntington, W. Va.; E. Dwight Barnett, New York; John W. Cline, San Francisco; Cleon A. Nafe, Indianapolis; and Willard A. Wright, Williston, N. D.

CONCLUSIONS

The conferees concluded that (1) physicians placement is a necessary service for which there is a continuing need; although it is primarily a state responsibility, its present degree of successful development as well as its useful future depend upon coordination and leadership from the A. M. A.; (2) there are varying degrees of positive approach at state level to a constructive placement program, based upon indigenous considerations; (3) there should be a minimum standardization on the essentials of a successful placement program with regard to basic technique and objective without forcing unwanted policy upon the individual state; (4) field work is essential in the matter of educating communities in responsibilities and in surveying need; (5) there are common problems that ought to have the best cooperative thinking of the several constituent societies; and (6) the criteria for priority rating developed by the Council on Medical Service is a splendid positive approach in evaluating community need.

MEDICAL MOTION PICTURES

Man in the Window: 16 mm., black and white, sound, showing time 28 minutes. Produced in 1952 by Victor Weingarten, New York, for, and procurable on loan or purchase ($45.00) from, Health Information Foundation, 420 Lexington Ave., New York 17.

This is the story of a recalcitrant old watchmaker who accidentally injures his right hand and becomes incapacitated. One of his customers, with whom he is on a basis of pseudo-antagonistic friendship, is a physical therapist. Following a number of fruitless attempts to resume his regular work, the watchmaker accepts the friend's advice and submits to a series of physical therapeutic treatments which ultimately restore him to functional efficiency. Medically, the film is entirely satisfactory except for one point, namely, the involvement of the joint after an apparently minor hand injury. The film includes some well-selected scenes from actual physical therapy procedures carried out at Bellevue Hospital. This is a frank recruitment plea for physical therapists and is suitable for showing to lay audiences, including adult groups and children of secondary school age. The photographic quality is excellent, but the sound quality is poor.

Baby Care: Feeding: 16 mm., black and white, sound, showing time 24 minutes. Produced in 1944 by Pennsylvania State College. Procurable on loan from Pennsylvania State College, State College, Pa., or on purchase from Educational Film Library Association, Inc., 1600 Broadway, Suite 1000, New York 19, N. Y.

The film is divided into two major sequences: correct feeding of the baby, and baby's food. It depicts the more accepted procedures, at present, in the science and art of infant feeding. The introductory scenes show a mother gently awakening the baby for his feeding. This is followed by a sequence illustrating the proper method of feeding the baby, which includes both bottle feeding and breast feeding. The second half of the film is devoted to a step by step picturization of the preparation of a day's supply of the infant's formula. Flashbacks review important points in preparation of the food and feeding of the baby as the commentator summarizes the film. The chief point brought out in this film is the importance of cleanliness and how to maintain it in the feeding of small babies. This film will be useful in the instruction of mothers, Red Cross classes, practical nurses, social workers, and junior and senior high school girls in the technique of feeding infants. The photographic and sound qualities are good.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Health and Accident Insurance: Total Disability in Relation to Physicians.—This was an action to recover under two health and accident policies issued to the plaintiff physician who instituted the actions. The physician died after an appeal of the case to the Supreme Court, and his wife was substituted as a party in his stead. From a judgment in the trial court in favor of the plaintiff physician, the defendant insurance company appealed to the Supreme Court of Minnesota.

The plaintiff was born in 1882. In 1909 he was licensed as a physician by the state of Minnesota. After eight years of general practice, he returned to medical school for a year of postgraduate work in obstetrics and gynecology and thereafter engaged in no other field of practice. In 1937 and later in 1944, the plaintiff purchased policies of health and accident insurance from the defendant. Each of these policies had stamped on the application the information that the plaintiff was a physician and surgeon specializing in obstetrics and gynecology. Each of the policies provided "If such injuries, as described in the insuring clause, do not result in any of the above mentioned specific losses, but shall wholly and continuously disable the insured for one day or more, the company will pay a monthly indemnity at the rate of the regular monthly benefit so long as the insured lives and suffers said total loss of time" and ". . . no reduction shall be made in any indemnity herein provided by reason of change in the occupation of the insured or by reason of his doing any act or other thing pertaining to any other occupation."

The injury that the plaintiff suffered left him with a permanent impairment. He sustained a rupture of the biceps tendon of his right arm and an acute sprain of the acromic clavicular joint as the result of an accident in his home while lifting a heavy piece of furniture in the process of laying a rug. On April 7, 1947, the plaintiff underwent an operation on his arm. A large clot was removed, and the biceps tendon that had been pulled loose from its fastening at the elbow was sutured to the triceps, another muscle in the upper arm. After 10 days in the hospital, he was discharged. He continued to suffer considerable pain and consulted a physician almost every other week until February, 1948. During this time, heat treatments, massage, and instruction in muscle reeducation were given. During the summer of 1947, there was gradual improvement, but attacks of severe pain of 3 to 10 days' duration occurred every two weeks. There was constant cramping of the muscle in the arms and pain similar to that felt when one strikes his "crazy bone." In January, 1948, a nerve block by infiltration of procaine hydrochloride (Novocaine) and quinine neuria hydrochloride was performed in an attempt to cut off the pain in the arm. The injection was repeated about a week later. The plaintiff continued to feel dull pain in his arm and was hampered by cramps when the arm was used. An examination of plaintiff just prior to the trial indicated a continued weakness in the right arm when tested against resistance. The biceps muscle was flabby, and there was a depression in the arm just above the elbow. There was a 50% loss of power in the biceps. Grasp in the right hand was 30 lb. (13.6 kg.), while in the left hand, roughly normal, the plaintiff could exert 60 lb. (27.2 kg.). Grasping power of the right hand was about one-third of what it should have been. There was an estimated 50% loss of ability in the pulling back motion of the arm, and the plaintiff experienced difficulty and pain in supination and pronation of the hand, especially when his arm was extended. He was unable to turn his arm over in front of him. The medical witnesses were of the opinion that this inability and weakness were permanent. One physician estimated a probable 15% loss of use of all functions of the right arm and hand. In the practice of obstetrics, said the court, there are certain techniques and functions that require the obstetrician to rotate his hand from the position of supination to that of pronation. Since he was unable to make these movements, he was unable to perform the work required of an obstetrician. Also, in a large number of obstetric cases, forceps must be used. It is necessary to grasp the forceps and to turn the hand over from a position of pronation to supination or from supination to pronation. The plaintiff was unable to do this. Also, in connection with the delivery of babies, a physician must, in the great majority of cases, perform an episiotomy. This the plaintiff was unable to do because he experienced a cramp when he had to clamp down on his needle forceps. He could not use any instruments requiring a grip. In operations, after his return to work, plaintiff would make the incision and the exploration, and then his associate would take over. Plaintiff would help hold the retractor and did other work requiring the use of his left hand. He had difficulty in taking blood pressure because of lack of strength to squeeze the bulb and had to depend on his nurse to do that. She also had to help him raise patients on the examination table. Whenever he attempted to lift anything, he had pain in his right arm. There can be no question on the record that the plaintiff was totally disabled from doing any work until he returned to his office, and after his return he did not try to conduct any operations unaided. If he had not been able to arrange for an assistant, the record indicated he would have had to stop work.

The defendant insurance company contended that the terms of the policies insuring against injuries that "wholly and continuously disable" the insured and that cause "total loss of time" are not ambiguous in themselves, that "total loss of time" should not be limited so as to mean total loss of time in the business or occupation or profession of the insured, and that where the terms of the policy do not specifically limit the meaning of the loss the court cannot insert such limitation. The plaintiff contended that the words "loss of time" as used in the policies means loss of business time from the occupation stated in the application for insurance, that the policies, when considered as a whole, showed that insurers and insured intended "occupational disability" insurance, and that to limit the coverage would mean a forfeiture of rights that the insured supposed he acquired.

Where clarification of the literal meaning of the terms of the contract is necessary but the nature of the limitation is not stated in apt words in the policy, said the court, this court, when presented with a question of the extent of coverage, must decide what the intention of the parties is as to the extent of the limitation of the literal meaning of the words. The literal meaning of the policy terms must be limited to some extent. The extent of the limitation does not appear in the policy. Different interpretations of the words is reasonably possible. We then have a contract that is ambiguous, the court determined. Where one of the parties draws a contract and the other must accept or reject but cannot vary the terms, the burden is on the party drawing the contract to make the meaning plain. Where meaning is thus uncertain, as it is in contracts here involved, the ambiguities and doubts must be resolved against the party who prepared the contract. Since the policies failed to state whether "loss of time," which means loss of earnings, must be incurred in insured's specific occupation or in some other occupation, the court must read something into the policies. A layman reading the policies in question would naturally conclude that "loss of time" with nothing more said, means loss of business time in the occupation of the insured. The circumstances of the issuance of the policies, with their stamped and written notations, although the policies say nothing as to loss of time from the insured's particular occupation, surround them with an air of occupational coverage. In our opinion, the court concluded, the contracts here are clearly ambiguous and should not be construed restrictively. It would seem that this is the sort of case in which the well-settled rule of construction against the insurer should be applied. It would seem that, even if the policies in their entirety do not indicate the intention of the parties, the contracts, being ambiguous, should be interpreted against the insurer. Adopting this approach, it must be held that the policies insure against disability to do the substantial and material acts of the insured's usual profession or occupation.

Accordingly the judgment of the trial court in favor of the plaintiff physician was affirmed. *Weum v. Mutual Benefit Health & Accident Ass'n., 54 N.W. (2d) 20 (Minnesota, 1952).*

BUSINESS PRACTICE

DETERMINING THE FEE

The following material was adapted from a public relat
manual issued by the Public Relations Department of
American Medical Association.—Ed.

The business side of medical practice gives rise to m
public relations problems. Patients may complain about
amount of the physician's fee, the way the bill is rende
or the manner in which it was collected. One of the
hurdles is the attitude of both doctor and patient toward m
cal fees. Although the doctor is a professional man, if
is to survive he must also be a businessman. Patients m
be encouraged to develop a realistic attitude about med
fees. Almost everyone who incurs doctor or hospital or c
bills has a hidden, if not overt, resentment about these c
The patient's attitude is "I didn't want to be sick. Now
stuck with all these bills." Paying medical bills is not
paying for a new car or television set or even a new s
A patient rarely has anything tangible to show for his m
cal purchase. His gratitude for the doctor's services o
fades fast once he begins to recover. It is essential that
tients learn to look on medical expenditures as a sound
vestment in their futures. Patients, too, must be taught
accept the doctor's right to charge a fair price for his hum
tarian services. The answer lies in mutual understanding
the financial problems of both doctors and patients.

There is no excuse for overcharging of any kind. A med
leader warns: "When you take the heart out of medicine
substitute a dollar sign, you are doing medicine a grave
service." Dr. Louis H. Bauer, A. M. A. past president, s
in his inaugural address: "Unfortunately, there are a
physicians who consider the practice of medicine as a me
of financial gain and that alone. Such individuals should
driven out of their medical societies. A physician who cha
exorbitant fees or who, when summoned in an emerger
refuses to make the call unless assured that the patient
pay, is a disgrace to the profession. Only a few are gu
of such practices, but those few do the profession incalcula
harm." In a constructive step toward improving public r
tions and doing a little "professional housecleaning," med
societies, with A. M. A. impetus, have in recent years
up mediation or grievance committees to hear and se
patients' complaints, the majority of which are about fe
The difference between high fees and excessive fees must
recognized, however. Some physicians, who have spent ac
tional years training to be specialists, and who, by nature
their practice have greater expenses, deserve a higher fee
their services.

Fees that are too low drive patients away just as quic
as do fees that are too high. A new doctor alienates ot
physicians if he undercuts local fees, and his patients sc
begin to wonder whether his fees are lower because he gi
service of a poorer quality. A doctor must avoid belittling
own services in conversations with his patients; for examp
a city physician soothed a patient about to undergo an app
dectomy by assuring her that "there was really nothing to i
Later the husband complained that the bill was too hi
"After all, you said yourself there was nothing to the ope
tion," he argued. Since it is wrong to charge too much, a
dangerous to charge too little, how can a doctor know j
how much to charge? The fair price is best. Most perso
are not looking for bargains in medicine. The average pers
is willing to pay a fair price for good medical service. A f
price can be arrived at only through a frank discussion wi
the patient.

Sycosis Barbae Due to Trichophyton Rubrum (Purpureum): Report of Case. J. S. Ludwig.—p. 216.

Nonsurgical Treatment of Cutaneous Beryllium Granuloma.—There appears to be almost unanimous agreement that surgical intervention is the only treatment for cutaneous beryllium granuloma. The patient whose case is presented sustained lacerations on two fingers from a broken fluorescent bulb containing beryllium silicate. The wounds were sutured within one hour after the accident. Two weeks later, the tissues broke down and ulcerated, and three months later there were indolent ulcers of the skin over the distal interphalangeal joints of the third and fourth fingers of the right hand. The lesions on the fourth finger extended across the entire dorsal aspect of the phalanx and over to the mesial surface. The microscopic diagnosis was consistent with beryllium granuloma. Four months after the injury was sustained, the lesions were essentially unchanged. The patient was advised that the ulcers should be widely excised and plastic repair should be performed. This the patient refused. Boric acid ointment was applied to both lesions, and the distal interphalangeal joints of the third and fourth right fingers were immobilized with wooden splints. One month after this treatment was instituted, the smaller lesions on the middle finger had healed. However, the larger ulcer on the fourth finger was more tender and the zone of erythema was more pronounced. An ointment consisting of 5% cortisone in an oxycholesterol-petrolatum ointment was then prescribed. The patient was instructed to massage the ointment into the lesion twice daily and to keep the lesion covered with the ointment in the intervals between massage. The finger was no longer splinted. Ten days after the first application of the cortisone ointment, the lesion became less tender and the zone of erythema less marked, and there seemed to be some evidence of healing of the ulcer. The improvement continued steadily, and two months later, the lesion had healed completely. A roentgenogram at this time revealed that the previously reported osteoporosis had cleared.

Treatment of Hyperkalemia in Acute Renal Failure.—Of 10 patients with acute renal failure and oliguria who were treated by conservative methods, 4 were given an ammonium carboxylate cation exchange resin free from potassium by mouth. Three adults were given approximately 50 gm. of the resin daily, and the child 20 gm. daily. The resin mixed with dextrose and water to form a not unpalatable pasty mixture was given hourly or every other hour to prevent undue nausea and to cause greater dispersion of the resin throughout the intestine. The daily serum potassium concentration uniformly rose in the patients receiving no resin. In the patients receiving resin, the levels fell uniformly. Excretion of potassium in the stool in one patient receiving resin amounted to 215 mEq. over four days. Though all the patients receiving resin were nauseated to some degree, they tolerated the resin well. The authors conclude that cation exchange resins constitute an efficient means of reducing hyperkalemia or preventing its occurrence.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Treatment of Rheumatoid Arthritis.—Forty-four patients with active rheumatoid arthritis were treated with a combination of *p*-aminobenzoate and acetylsalicylic acid. The potassium salt of *p*-aminobenzoic acid was given in six doses daily of 2 gm. each. Generally 20 cc. of a 10% solution of potassium *p*-aminobenzoate was taken with each meal and midmorning, midafternoon, and at bedtime. Acetylsalicylic acid was administered in a dosage of 0.6 gm. four times daily taken at mealtime and at bedtime. Some patients also received 25 mg. of cortisone daily, but the combined use of the small amounts of the latter drug with *p*-aminobenzoic acid and acetylsalicylic acid did not result in any significant change in eosinophil counts or in 17-ketosteroid excretion. Of the 44 patients, 34 (77%) showed functional improvement evidenced by increased range of motion, striking weight gain, and diminution in joint heat, swelling, pain, and tenderness. Although striking improvement was occasionally seen after two or three weeks, the more usual course was a gradual betterment that culminated in significant improvement after three months of treatment. This improvement was maintained for from 6 to 18 months. Untoward reactions were minimal and readily reversible when use of the drugs was discontinued. Three patients had relapses when placed on placebo therapy. Two of these were treated again, with highly satisfactory suppression of the disease process. Three additional patients had relapses when treatment was stopped deliberately or because of intercurrent illness. Resumption of therapy was again followed by improvement. These observations seem to indicate clearly that the relationship between therapy and response has been too consistent to be attributed to chance remission. It should be stressed, however, that this treatment program does not cure rheumatoid arthritis. It appears logical to conclude that a true synergism is exerted by high dosage of *p*-aminobenzoate with acetylsalicylic acid. The combined use of these drugs is suppressive therapy, which frequently results in significant functional improvement.

Myoclonus Epilepsy in Diffuse Neuronal Disease.—Watson and Denny-Brown state that Unverricht and Lundborg described a progressive familial syndrome of myoclonus epilepsy, the fully developed form of which was additionally characterized by progressive dementia, pseudobulbar paralysis, rigidity, and, in the late stages, quadriplegia in flexion. Diverse types of nerve cell changes have been reported in patients with this syndrome, either diffuse, "primary atrophy" or diffuse cellular changes characterized by cellular inclusions. Though descriptions of myoclonus epilepsy almost always refer to the curious dark-staining "amyloid" inclusions, this type appears to be extremely rare. A more frequent finding has been the lipoidal inclusions characteristic of amaurotic familial idiocy. Juvenile amaurotic familial idiocy has been recognized as a distinct clinical type of lipidosis of the nervous system. It is to be distinguished from the infantile form of amaurotic familial idiocy, the infantile and juvenile forms never having been reported in the same family. The appearance of epilepsy in childhood, between the ages of 6 and 12 years, in association with a progressive extrapyramidal type of rigidity, leading to dysarthria and dystonic abnormalities of gait and ultimately to a state of general flexion contracture of the limbs and body, has often been described in this disease. Nearly all patients with juvenile amaurotic familial idiocy are reported to have had epileptic seizures. There is frequent mention of sudden jerking of the limbs. Few authors have noted that such myoclonic jerking movements bring this familial disease within the clinical definition of myoclonus epilepsy. Two families exhibiting the syndrome of progressive myoclonus epilepsy are described. Two siblings of family 1 displayed the typical syndrome of progressive familial myoclonus epilepsy of the type described by Unverricht and Lundborg. An affected member of family 1 was found to have diffuse neuronal lipidosis ("cerebromacular degeneration"). Neither of the affected siblings had visual defect or pathological change in the fundus. Family 2 differed from family 1 in several important respects: Epileptic attacks in the form of self-limiting seizures of childhood occurred in one generation and partial or arrested forms of the syndrome in the other. The syndrome followed a more benign and remitting course than that in family 1. The pathological process in the second family was not verified, but a review of the problem of myoclonus epilepsy indicates that it uniformly results from diffuse neuronal disease.

Ménière's Syndrome.—Atkinson reported in 1949 and 1950 investigations along nutritional lines in 87 patients with Ménière's syndrome. These studies demonstrated that patients can be divided by means of a histamine skin test into three groups: one in which the mechanism is primarily vasoconstrictor; another in which the mechanism is vasodilator; and a third, an intermediate group, in which the attacks are now one and now the other. All three groups show signs of chronic severe deficiency of the vitamin B complex; the signs in the vasoconstrictor group are those of a predominant nicotinic acid deficiency; the signs in the vasodilator group are those of a predominant riboflavin deficiency; and the signs in the intermediate group are those of a mixed deficiency of both nicotinic acid and riboflavin. All three groups show some evidence of thiamine deficiency, but this does not appear to be the determining factor. The attacks of vertigo can be controlled by administration of the appropriate vitamins in suitable dosage, and tinnitus often can be considerably improved and occasionally entirely relieved with the same regimen, but deafness can only rarely be modified. This therapeutic regimen together with attention to proper dietary habits also greatly improved the general health of the patients. An additional group of 105 patients has been investigated along identical lines and the clinical observations and the therapeutic results confirm those previously described. It is now the author's practice in every case of Ménière's syndrome to obtain a detailed record of the intake of food, fluid, alcohol, and drugs and of the use of tobacco for seven consecutive days and a history of dietary habits in general in the past, special dietary restrictions if any, and so on. When such a record is taken it is surprising to find how inadequate in many essentials, how ill-balanced and often injudicious is the diet even of people who might be expected to know and to do better. Patients in the age group in which Ménière's syndrome commonly arises, 40 to 60, require a high protein, high vitamin, moderate to low carbohydrate, and low fat diet. It is a rarity to find such a diet. Yet if patients with Ménière's syndrome are to be restored to full health and efficiency and not merely relieved of their attacks, insistence on such a diet is essential.

Sinusitis as Focus of Infection in Eye Lesions.—Weille and Vang point out that questioning of the eye surgeons at the Massachusetts Eye and Ear Infirmary revealed that none denied the possibility of sinus foci in causing eye disease, but they considered such a relationship to be rare. Infected teeth, tonsils, and prostates were most commonly held responsible, but the sinuses only rarely and then usually by direct extension of infection to the orbit. The pathological physiology of a sinus focus of infection is discussed. Attention is given to toxemia, lymphangitis and bacteremia, bacterial allergy, nasal reflexes in relation to the eye, and direct extension. The files of the Massachusetts Eye and Ear Infirmary were searched for cases of uveitis, optic neuritis, and keratitis, and efforts were made to determine which patients had undergone a search made for foci of infection and more particularly for sinus infection. Of 668 cases studied, there were 427 of uveitis, 43 of optic neuritis, and 198 of keratitis. The three groups of patients are discussed not only with regard to the presence of foci of infection, particularly in the sinuses, but also with regard to the effects of surgical treatment of the sinus lesions on the eye lesions. The authors gained the impression that if the sinusitis is such as to require treatment on its own merits, whatever management is indicated, whether medical or surgical, should be carried out. The attempt to eradicate sinus disease in order to cure uveitis may be undertaken if the rhinologist, the ophthalmologist, and the patient all understand clearly that such therapy only occasionally is useful as far as the eye disease is concerned. Controversy rages regarding the importance of sinusitis in keratitis, especially in that complicating corneal transplants. Ophthalmologic surgeons at the Massachusetts Eye and Ear Infirmary are skeptical of any basic relationship. As regards retrobulbar neuritis, the authors say that dehiscences in posterior ethmoid cell walls in close relationship to the optic nerve are common. Posterior ethmoiditis is extremely common in clinical practice, but its association with retrobulbar neuritis is rare. This is true also of sphenoiditis, although sphenoidal dehiscences in relation to the optic nerve and optic chiasm are frequent. Of 38 cases of retrobulbar neuritis in which search for foci was carried out, sinusitis could be found in only 4. In one it was an obvious cause of retrobulbar neuritis incidental to massive infection, which caused death within one week.

Recurrences and Metastases in Cancer of the Breast.—One hundred women with cancer of the breast, one of whom is living at the present time, are reviewed with special emphasis on the time of appearance of recurrences and metastases after the estimated onset of the disease. The peak age incidence was in the 40 to 50 year group. Of the 100 patients, 76 were given surgical treatment combined with roentgen therapy, 15 had roentgen therapy alone, 6 had surgical treatment alone, and 3 had no treatment of any kind. Roentgen therapy added to surgical treatment did not improve the survival rate. The arithmetical mean number of years between the estimated onset of the disease and death for the group as a whole was three to four years. The arithmetical mean number of years between the estimated onset of the disease and the appearance of recurrences or metastases was two to three years. Of the 100 patients, 92 had recurrences or metastases, 67 of the 92 had one recurrence or metastasis, 19 had two recurrences or metastases, and 6 had three or more recurrences or metastases. By considering the interval of time between the estimated onset of the disease and the appearance of the first, second, third, or more recurrences or metastases it was calculated that 70 to 90% of those patients in whom recurrences or metastases from cancer of the breast develop will have the first recurrence within three years after the onset of the disease. Of those patients who have two or more recurrences or metastases from cancer of the breast, 59 to 96% will have these within four years after the estimated onset of the disease. In the 100 patients studied no clear cut cyclic tendency in the appearance of recurrences or metastases was demonstrated.

Primary Amyloidosis with Involvement of the Stomach.—According to Cooley, primary amyloidosis is a rare disease that most frequently involves the heart, but, in addition, often invades the stomach and the remainder of the gastrointestinal tract. Despite the high incidence of gastrointestinal involvement, definite signs or symptoms of involvement of the stomach, which dominated the clinical picture, were observed in only seven cases collected from the literature. In these cases hematemesis, abdominal pain, and vomiting secondary to pyloric obstruction were most frequent. Changes observed in the stomach at autopsy were (1) infiltration of amyloid in the adventitia and ambient areas of the small blood vessels in the submucosa; (2) replacement of the portions of the muscular wall of the stomach by amyloid; (3) atrophy of the mucous membrane of the stomach that is usually extensive and associated with necrosis, degeneration of the glandular cells, and infiltration of amyloid between the cells; (4) multiple erosions of the mucous membrane with hemorrhage, and (5) ulceration of the stomach wall similar to that seen in peptic ulcer. The occurrence of primary amyloidosis with involvement of the stomach is reported in a 59-year-old man whose case was similar in many respects to the seven cases collected from the literature. There was roentgenologic evidence of an ulcer 2 cm. in diameter on the lesser curvature of the stomach. The lesion healed rapidly on a medical regimen and could not be demonstrated at operation five weeks later. This ulceration was in close relationship to an area of pronounced amyloid thickening of the stomach wall. A complicating feature was that symptoms first appeared and the ulcer was first noticed while the patient was receiving doses of from 200 to 160 mg. of corticotropin (ACTH). A tendency toward ulceration of the area of amyloid infiltration probably was enhanced by the administration of corticotropin. There is a pronounced similarity of the roentgenologic manifestations of amyloid deposits in the stomach to those seen in gastric cancer. It is impossible to differentiate between the two on roentgenologic evidence alone. In no case recorded in the literature has the amyloid deposit in the stomach been an isolated occurrence, but this does not clarify the issue since carcinoma of the stomach may occur in the presence of diffuse amyloidosis.

Aschoff Bodies in Auricular Appendages of Patients with Mitral Stenosis.—A total of 183 left auricular appendages that were removed during interventions for mitral stenosis were studied to detect the presence of Aschoff bodies. The authors found them in 83 (45.3%) of the appendages. They were located within the endocardium and oftener in the loose-structured subendocardium. This incidence of Aschoff bodies does not differ greatly from that found by other authors at autopsy on patients with rheumatic heart disease. The authors studied 172 of these appendages to detect the presence of old or recent thrombosis. Both types of thrombi were found, but old organized thrombi were commoner. There was thrombosis in 71 (41.3%) appendages, and Aschoff lesions were present in only 7 of these 71. These findings are in agreement with those of other workers who have reported a decreased incidence of rheumatic activity in the presence of auricular thrombosis. Autopsy was performed on 22 of the patients of this study, including 6 in whose appendages Aschoff bodies were found. Autopsy revealed these bodies in the remainder of the heart of five of these six patients. Although the number of patients studied is too small for a final statement, the authors conclude that the presence of Aschoff bodies in the auricular appendage is paralleled by their presence in the rest of the heart and, as in their cases, they are located mainly in the left ventricular myocardium.

Hypertension and Coronary Occlusion in Men and Women.—The author studied 500 men and 100 women (consecutive private patients), all under the age of 65, with coronary occlusion to reexamine the problem of the relationship between hypertension and coronary disease. The blood pressure had been recorded before the attack in 478 of these patients. For the others informations were given by the referring physicians or by the patients themselves. The author based his study on the new limits of hypertension that Master, Dublin, and Marks recently established with respect to a person's age and sex. They based their values on a study in which they sampled and analyzed statistically the blood pressure readings of 74,000 working men and women between the ages of 16 and 65 years. According to their new values, almost half of the men (48.6%) had the coronary attack between the ages of 50 and 60 years (average age, 51.1 years). Only 27% of them had had hypertension before the occurrence of coronary occlusion, and it had increased slightly, if at all, with age. More than 70% of them had had normal blood pressure, thus suggesting that if hypertension is at all a factor causing coronary occlusion in men it is not the most important factor. Women had the coronary attack at a later age (average age, 54.8 years). Hypertension had been present in 71% of them before the occlusion occurred. It thus appears to be a definite factor in producing coronary disease among women. A recent postmortem study by Zeman and Schwartz confirmed these findings. Hypertension does not seem to be a factor responsible for coronary disease and occlusion in men, whereas it is a definite factor for their causation in women. In previous studies on hypertension in women it was found that arterial tension is slightly higher in women, beginning at the age of 45 to 50, than in men. The difference is small but distinct. Whether it is sufficient to initiate or accelerate the process of atherosclerosis in women at the age of 55 to 60 is questionable. The serum cholesterol and S_f 12-20 lipoprotein ratios are higher in patients with hypertension, and they may be factors through which hypertension accelerates atherosclerosis.

Methonium Salts and Hydrazinophthalazine in Hypertension.—The authors report the effects of hexamethonium and pentamethonium administered intravenously and orally and of hydrazinophthalazine administered alone and concurrently with hexamethonium to patients with hypertension. Oral and intravenous administration of hexamethonium or pentamethonium caused an initial moderate reduction in blood pressure. The initial response was greater in patients with malignant hypertension who had reduced serum concentration of sodium or severe encephalopathy. The response to the drugs was increased by sodium depletion or severe encephalopathy. The methonium salts inhibited the ganglionic conduction with reduction of sympathetic vasoconstrictor tone and partial inhibition of reflexes through the sympathetic and parasympathetic nervous systems. Continued oral administration of the drugs caused diminished response to either drug. The effects of reduction in pressure by oral administration of hexamethonium were renal insufficiency terminating in uremia, evidence of myocardial and renal ischemia, and transient loss of vision. Since all the patients in whom these effects occurred had malignant hypertension, it is suggested that the danger of reduced blood flow to the kidneys, heart, retina, and brain is greater in these patients. Side-effects of the drugs were dryness of the mouth, slight blurring of vision, increased warmth of the extremities, and chilly sensations. They were mild and did not require any therapeutic measure. Hydrazinophthalazine produced a slight to moderate reduction in pressure in about half the patients studied. With concurrent administration of hexamethonium the reduction in pressure was greater than when either drug was given alone. Tolerance to the hypotensive effect of the drug developed more slowly, and the postural hypotension was less pronounced than that following hexamethonium given alone. Similar degrees of postural hypotension appeared to be somewhat better tolerated. The effect of the two drugs on the blood pressure appeared to be approximately additive in most patients. In none of the patients was there more than mild and transient reduction of renal function following reduction in blood pressure by hydrazinophthalazine or by this drug combined with hexamethonium. Although it did not increase the renal blood flow significantly, hydrazinophthalazine appeared to lessen the effect of reduced blood pressure by intravenous administration of hexamethonium on renal blood flow and glomerular filtration. The side-effects of hydrazinophthalazine were headache and conjunctivitis, sometimes hiccups and elevated temperature. Concurrent administration of this drug and hexamethonium enables a greater and more prolonged reduction in blood pressure than administration of hexamethonium alone, and fewer untoward effects may occur after comparable reduction in blood pressure. It may also be desirable to administer hydrazinophthalazine before hexamethonium.

Electrocoagulation of Hypophysis in Cushing's Syndrome.—A typical advanced case of Cushing's syndrome is described in a 24-year-old woman. She was given two courses of irradiation of the hypophysis, one in July and one in November, 1943; 1,500 r were given in each of the two series and resulted in the disappearance of all symptoms of the syndrome by the beginning of 1944. Symptoms reappeared during the spring of 1948 and she was again treated by irradiation of the hypophysis in September, 1948, with some temporary improvement. On examination in April, 1950, the disease was more advanced and retreatment with massive doses of roentgen rays (4,500 r) was ineffective. There was pronounced obesity of the buffalo type with thin extremities and a fullmoon face. Pronounced hypertrichosis was localized in the face, thorax, abdomen, and extremities. The patient had numerous purple striae on the hips and abdomen, ecchymoses, and severe acne of the face and upper thorax. Blood pressure at rest was 200/130 mm. Hg, and the heart was enlarged to the left. There was increased excretion of reducing corticoids. An adrenocortical tumor had been excluded in 1943 by means of perirenal insufflation of air and palpation of the adrenal glands at an exploratory laparotomy. In June, 1951, an attempt was made to destroy the hypophysis by electrocoagulation in order to abolish the presumed hypersecretion of the adrenocorticotropic hormone. The pituitary region was exposed by a rather small pituitary flap and the arachnoid in the cisterna chiasmatica removed as completely as possible. Electrocoagulation of the pituitary gland was then performed in two stages with an interval of 10 days. During the first stage electrocoagulation was carried out in 7 different places and in 13 during the second stage. All symptoms remained unchanged after the first stage, but rapid improvement, which was obvious after 10 days, occurred after the second operation. Three weeks after the last operation the patient had her first menstruation in three and a half years. Menstruation has remained regular since, the patient continued to lose weight, blood pressure showed a gradual decline, and her habitus became normal. She became pregnant 14 months after the operation, a legal abortion was performed, and menstruation reappeared the next month. The patient is still healthy 19 months after the operation. The electrocoagulation did not cause complete destruction of the pituitary gland, as the gonads, thyroid, and adrenals showed normal function. The result of the operation, i. e., the clinical cure of the patient in association with normally functioning hypophysis and adrenal cortices, strongly suggests the etiological significance of the pituitary gland in this case of Cushing's syndrome.

*Bleeding Esophageal Varices and Their Surgical Treatment. R. R. Linton.—p. 400.

Bleeding Esophageal Varices.—Esophageal varices are a constant and serious threat to the life of the patient in whom they occur because the exsanguinating hemorrhages following their rupture frequently result in death. The cause of the rupture, which invariably takes place within a few centimeters of the cardioesophageal junction, although the varices may extend the entire length of the esophagus, has never been satisfactorily explained. The incidence of fatal hemorrhage is much higher among patients with esophageal varices secondary to cirrhosis of the liver than it is among those with Banti's disease, who are usually younger. Treatment of patients with bleeding esophageal varices requires emergency control of the hemorrhage, followed by the construction of a portacaval shunt to bring about a permanent reduction in portal hypertension and thus prevent further rupture of the varices. Cardioesophageal tamponade with an intragastric balloon tube, supplemented by immediate transesophageal suture of the varices, is recommended as the best emergency method of controlling the massive bleeding in these patients when it does not stop spontaneously. The great advantage offered by this method is that, once the bleeding is controlled, the patient's condition can be built up more satisfactorily with proper food and vitamins than when any other method is employed. The definitive procedure, or construction of the portacaval shunt, should be undertaken as soon as the patient's condition warrants, usually at the end of three or four weeks. The two types of portacaval shunts that have proved most effective are (1) an end-to-side splenorenal anastomosis with splenectomy, and (2) a direct portal vein-to-inferior vena cava anastomosis. The choice of the type to be used depends largely on the size of the spleen, the condition of the patient, and the degree of liver impairment. A surgeon should not attempt a splenectomy in a patient with bleeding esophageal varices unless he is prepared to carry out a splenorenal anastomosis at the same operation, because it may be his only chance to construct a satisfactory shunt, especially in patients with Banti's disease. Portacaval shunt operations should never be undertaken for the relief of chronic ascites alone. Results obtained by the construction of portacaval shunts in 90 patients treated at the Massachusetts General Hospital since 1945 have been extremely encouraging; 77, or 86%, of the patients survived, an operative mortality rate of 14%. Most of the deaths occurred in the earlier years, so that the mortality rate for the last 60 shunts performed was only 5% (three deaths).

Pulmonary Tension Disorders in Infants and Children.—The primary causes of pulmonary tension rarefactions in the lungs of infants and children are congenital bronchial malformations and acquired interstitial and pleural air cysts. In both groups tension states develop as a result of check valve mechanisms between the distended cavity and its air supply. Differentiation of the acquired from the congenital forms is important to prognosis and treatment, and this is best accomplished by careful correlation of the roentgen and clinical findings. Serial chest roentgenograms are the most important single aid in differential diagnosis. Occasionally bronchography and planigraphy will make possible recognition of these lesions. In the congenital group, complete surgical removal is the only definitive treatment for all but the generalized forms, while the acquired lesions are best treated conservatively. Accurate roentgenologic differentiation of various tension disorders is sometimes impossible but a system of analysis is presented that should allow separation of the surgical from the nonsurgical types.

Differentiating and Preserving Protozoa in Feces.—A relatively simple method for the identification of the cysts and trophozoites of intestinal protozoa in feces is described. It is based on the wet fixation and staining of the organism with a mixture containing a single dye, brilliant cresyl blue. The staining solution has the following formula: brilliant cresyl blue (N. F. Biological), 2 gm., methanol, 75 cc., formaldehyde (U. S. P.), 5 cc., glacial acetic acid (U. S. P.), 2.5 cc., phenol (U. S. P.), 2.5 cc., and distilled water, 15 cc. After the solution is thoroughly mixed, it is ready for immediate use. No filtration is required. The liquid phenol is prepared by placing a bottle of phenol crystals in a hot water bath until liquefaction occurs. Best results are obtained when the ingredients are used in the proportions as given in the above formula. Should a weaker stain be desired, the solution may be diluted with distilled water. The solution is stable and, if stored in tightly stoppered brown glass containers, may be kept for long periods without deterioration. A small portion of the fecal material is mixed in a large drop of the staining solution on a clean slide. After a smooth emulsion is obtained, a coverglass is applied and an immediate microscopic examination may then be made. When the solution is used as a preservative for fecal specimens, one part of the fresh stool specimen is thoroughly mixed with about five parts of the solution in a glass vial or similar container. Such specimens may be examined weeks later, provided the container has been tightly stoppered. Permanent wet preparations may be made by sealing the cover slide with a ringing material. The authors examined stool specimens with this method and with iron-hematoxylin and found that the wet fixation and staining with the brilliant cresyl blue formula compared favorably with, and in some instances was superior to, the much more complicated iron-hematoxylin procedure.

Cardiac Catheterization in Chronic Pulmonary Conditions.—The prognostic value of catheterization of the right side of the heart was studied in a series of seven patients undergoing pneumonectomy, lobectomy, or extrapleural pneumothorax. Respiratory function values in all the patients were within the limits usually considered acceptable for the surgical procedures contemplated. Catheterization was performed before the operation in five patients and after it in all seven. Results showed that the interventions had comparatively little effect on the resting pressures in the right side of the heart and that the moderate increases in right systolic pressure seen in patients with chronic pulmonary disease need not be taken as contraindications to operation, because they may disappear after the operation. Study of the pressure in the right side of the heart at rest has, therefore, no prognostic value. The investigation was extended to 28 patients selected at random for whom no operation was proposed. Five of these had moderately advanced tuberculosis, 15 far advanced tuberculosis, 4 pulmonary sclerosis with emphysema, and 4 silicosis. Systolic ventricular and pulmonary arterial hypertension was found in 6 of the 20 patients with tuberculosis, but in spite of the extent of their pulmonary lesions none showed right ventricular insufficiency. Increased pressures were found in the patients with silicosis, all four of whom had severely impaired, enlarged hearts. Decompensation was present in three, and the fourth had sequelae of infarction. The pressure was increased in only one of the patients with pulmonary sclerosis and emphysema. Incipient or moderate right-sided hypertension could not be detected in the electrocardiograms of the patients studied.

Effect of Procaine Amide on Cardiac Arrhythmias.—Study of 28 patients with various types of cardiac arrhythmia confirmed the efficacy of procaine amide as an antiarrhythmic agent. It may be given by intravenous injection at the rate of 1 cc. a minute under electrocardiographic control so that administration can be stopped as soon as the rhythm becomes regular. The quantity injected may be from 300 mg. to 1 gm. The patient should be kept lying down for from 30 minutes to an hour after the injection and additional electrocardiograms should be made every 10 minutes to verify the persistence of the regular rhythm. Oral administration is also possible, but given in the doses of from 4 to 5 gm. daily required for effective suppression of ventricular extrasystoles, it caused significant digestive disturbances in the patients treated. Discontinuance of the drug was followed by recurrent extrasystoles. The need for large doses of procaine amide and the rather short duration of its action impose certain practical limitations on its use. The generally benign character of ventricular and atrial extrasystoles makes its administration in these disturbances of questionable value. Intravenous injections of procaine amide may put an immediate end to an attack of recent atrial fibrillation, but when the fibrillation is of long standing, the action of the drug, even in large doses, is uncertain. Procaine amide is especially valuable in paroxysmal ventricular tachycardia; a dose of 500 mg. effectively stopped an attack in one of the patients in this series, and larger doses may be used when necessary. Supraventricular paroxysmal tachycardia is also relieved by procaine amide; in this condition, its action resembles that of acetylcholine, breaking a vicious circle and thus enabling the heart to maintain a regular rhythm after the drug has disappeared from the blood. No electrocardiographic disturbances were noted, either in the patients or in experimental dogs, when procaine amide was used in therapeutic doses.

Dynamics of Circulation in Mitral Stenosis.—The 57 patients with mitral stenosis reviewed in this paper were selected from among 250 patients with rheumatic heart disease seen at the Institute of Cardiology, Royal Prince Alfred Hospital, in Sydney. Mitral stenosis was regarded as predominating on the following evidence: (1) a low rumbling diastolic murmur following the third sound or opening snap, usually with presystolic accentuation in patients with sinus rhythm; (2) a loud first sound at the mitral area; (3) a normal or, more frequently, a diminished left ventricular impulse to palpation; (4) absence of left ventricular preponderance in the electrocardiogram; (5) slight to moderate enlargement of the left auricle on fluoroscopy. The patients were studied by cardiac catheterization, with the use of a single or double lumen catheter. The great majority were in or near the basal state at the time of study. The patients had been placed on clinical grounds in the functional classes of the New York Heart Association. In the resting subject, as one passed from class 2 to class 4, the following changes in the dynamics of the circulation were found: (1) a decrease in valve area; (2) a rise in the arteriovenous oxygen difference and a fall in cardiac output and stroke volume—the oxygen consumption was unchanged; (3) a rise in pulmonary vascular pressure; (4) a rise in right auricular pressure. During exercise pulmonary vascular pressures rose out of proportion to the increase in cardiac output, which was determined chiefly by the laws governing mitral valve flow. On the whole there was a good correlation between the disability and the changes in the pulmonary circulation. On analysis of the data it became clear that patients with mitral stenosis fit into three hemodynamic stages. In the first stage the valve area is between the normal of 4 to 6 and 1.5 square centimeters. Pulmonary vascular pressures and cardiac output are within the normal range at rest; both rise on exercise to a degree determined largely by the severity of the stenosis. In the second stage the valve area is between 1.5 and 0.9 square centimeters. Pulmonary vascular pressures are raised at rest and rise even more on exercise. The cardiac output is maintained at rest by various compensatory mechanisms, the chief of which are probably right ventricular hypertrophy and a slightly raised filling pressure. During light exercise the cardiac output rises less than normally, and in some patients there is also a rise in filling pressure. It is during this second stage that rises in the pulmonary vascular resistance begin to appear. In the third stage the valve area is less than 0.9 square centimeter. Pulmonary vascular pressures are usually four times normal or even more, and the cardiac output at rest is low. The filling pressure has risen in the majority of these patients. During exercise pulmonary vascular pressures and filling pressures rise, but the increase in cardiac output is negligible. In most patients pulmonary vascular resistance rises greatly. Auricular fibrillation is not found usually before the second stage. A small number of patients with sinus rhythm resemble those with auricular fibrillation. The authors admit that the described studies cannot give information about many factors that must influence physicians and surgeons in chosing the optimal time for mitral valvotomy; but it seems advisable to recommend this operation before the cardiac output has fallen and organic changes have appeared in the pulmonary circulation. This would correspond to the stage of dyspnea on light exertion.

Breast-Feeding in Oxford Survey.—The progress of 580 babies in the Oxford Child Health Survey was studied in relation to feeding habits. At the age of one year the babies who were bottle-fed from birth were appreciably heavier than the babies who were completely breast-fed for five months or longer. They also showed signs of being slightly maturer. It is suggested that these differences are due to minor degrees of underfeeding among the breast-fed babies. To discover whether the accelerated growth and development in the bottle-fed babies was attended by any increased risk of ill health, the sickness records of the babies were examined. For three disease groups, namely gastroenteritis, bronchitis and bronchopneumonia, and otitis media and tonsillitis, there was no evidence that the duration of complete breast-feeding influenced the over-all infection rates. Gastroenteritis was comparatively rare so long as the babies were receiving nothing but breast milk, but it reached its maximum incidence in the weaning period and was especially common among babies who began to be weaned in the sixth month. Colds, which were most frequent in large households and households with several children of school age, were almost equally common among breast-fed and bottle-fed babies. That breast-feeding has advantages to both mother and child that will never show on a weight chart no pediatrician will seriously deny, but under conditions that prevail today the dangers of bottle-feeding are more potential than real. With artificial feeding now safe and easy, the slightest neglect of the special problems of nursing infants could produce a sharp popular reaction against breast-feeding.

Obesity as Diencephalohypophysial Dysregulation.—Of 24 obese women with adiposis of the trunk and of the extremities who were admitted to the medical clinic of the university of Homburg, Saar, the pathological obesity had become manifest after pregnancy ending in abortion or delivery in 10 and after menstrual disturbances in 9; one patient had a tumor of the pituitary, and another had been given *p*-acetylaminobenzaldehyde thiosemicarbazone (Amithiozone), which may exert an effect similar to that of cortisone. Physiological or pathological changes of the endocrine system thus were indicated in 21 of the 24 patients. Atrophy of the sex organs could be demonstrated on gynecologic examination in only 8 of the 9 women with menstrual disturbances, and the hypophysis was considered the cause of the obesity after abortion or delivery in 10. The authors believe that obesity in women between the second and fourth decade of life is caused endogenously by diencephalohypophysial dysregulation, while exogenous factors, such as polyphagia, play a secondary part only. This concept was supported by the results of the Staub-Traugott test that revealed pathological changes in the sense of a negative effect in 20 patients with a repeated elevation of the blood sugar level by 40 to 100 mg. per 100 cc. after the second oral dose of detxrose. Results of examination of the carbohydrate metabolism by insulin and epinephrine tests and of the water metabolism by Volhard's gravity test for renal function and by the water test after administration of an extract of the posterior lobe of the pituitary gland and after injection of thyroxin provided additional proof for the authors' concept. Passage of short waves through the region of the pituitary of the patients always caused an increase in the blood sugar level and an increase in granulocytes exceeding the physiological variation; the increase in the blood sugar level was considered as manifestation of a pathological reaction of the pituitary, while the increase in granulocytes was considered as manifestation of stimulation of the diencephalon. The weight of the anterior lobe of the pituitary is greater in women than in men; this, as well as the fact that the weight of the anterior lobe of the pituitary increases by 20% during pregnancy, may explain the predisposition of women to obesity. The increased incidence of obesity in the postwar period may be explained by the functional unity of hypophysis and diencephalon that makes it possible for hormonal dysfunction to be elicited by vegetative stimulation, and a diet deficient in protein may favor this development.

Congenital Fibrosarcoma.—The case reported is that of a baby girl hospitalized at the age of two months with a tumor in the mastoid region that had been present since birth and that had rapidly enlarged. The skin covering the tumor was pale red and shiny and showed dilated veins. The consistency was elastic; the tumor could not be moved freely. As the tumor was growing rapidly, a provisional diagnosis of sarcoma was made, and extirpation was carried out. The tumor bed was treated with electrocoagulation, but the patient died seven days after operation, with symptoms of meningoencephalitis several days before death. The tumor was classified as fibrosarcoma by reason of its structure and of the arrangement of the reticulin fibers and because of the absence of special structures or protoplasmatic differentiations, which would justify a diagnosis of neurosarcoma or of the not so rare rhabdomyosarcoma of the head or neck region. In one of the blocks of tissue, tumor tissue was found in a lymph node and in a lymph vessel. Since the tumor was present at birth and grew rapidly, a diagnosis of congenital fibrosarcoma seemed justified.

Nature and Classification of Onyalai. J. Wilkinson.—p. 243.
Intestinal Obstruction Due to Ascariasis. R. G. Romberg.—p. 251.

Endemic Dental Fluorosis in Kenya.—Williamson feels that the dental signs of fluorosis so far observed in the population of Kenya gives sufficient proof to warrant a fuller inquiry and survey on the following lines: (1) to check and analyze regularly all domestic water supplies, (2) to survey and map in detail endemic areas, (3) to undertake rock analyses for correlation, (4) to correlate the caries incidence with dental fluorosis in East Africa, (5) to publicize the possible serious effects of fluorides from a public health point of view, (6) to take adequate steps to reduce domestic water supplies to concentrations of less than one part per million, and (7) to investigate the possibility of skeletal changes in the indigenous population. Analysis of water supplies shows a predisposition toward high fluoride content. The geological structure of Kenya is such that one would expect high fluoride figures. Large areas of the country are covered by formations due to comparatively recent volcanic action. The surface waters percolate through the soil, in many areas consisting of high percentage of volcanic ash, and then pass through the weathered trachyte tuffs or lavas. Over 4,500 children and adults were examined in different parts of Kenya for signs of the varying degrees of mottled enamel. The degrees of dental fluorosis were classified according to Dean. It is important to note that the teeth are affected only if the ingestion of the fluoride takes place during the time of enamel calcification, that is, up to the age of 8 years, or about 12 if the third molars are to be included. Ingestion after this period then has a cumulative effect on the skeletal structure. The author believes that the medical profession in Kenya should take an interest in the effects of chronic fluoride intoxication. The following are indications of such intoxication: increased density of the bones, diminution of the medullary area, calcification of the ligamentous attachments, osteophytic growths, and exaggeration of the curvatures of certain of the long bones. Nearly 2,000 children with dental fluorosis were seen; the condition is endemic in Kenya and other parts of East Africa.

Acute Necrosis of Liver Following Chloramphenicol Therapy.—The 5-year-old boy whose history is reported was hospitalized while in a delirious condition on June 11, 1951. Death occurred on the day following admission. The family physician stated that the child had been well until nine weeks prior to admission, when whooping cough developed for which he prescribed a single course of chloramphenicol. Unfortunately the total dosage has not been recorded, but presumably it was not higher than 5 or 6 gm. and was spread over about one week. The boy made a rapid recovery. A fortnight before admission jaundice with pale stools was observed and was regarded as infective hepatitis. Jaundice seemed to clear, and the stool became normal in color three days before hospitalization. In the early morning of the day of admission, the boy had a severe epistaxis followed by two attacks of vomiting. He ate a good breakfast, but at noon vomited again, partly bright red blood. Thereafter he became delirious. Autopsy was done 18 hours after death, and microscopic studies disclosed a virtually complete disappearance of the liver parenchyma, the tissues consisting of the somewhat condensed reticulum framework and other mesenchymal elements, while the bile capillaries had survived. Only after searching were some shadows of liver cells found in some areas. An interesting feature was cellular damage in the cortex of the brain similar to that observed in the basal ganglia in kernicterus.

Disseminated Sclerosis.—Compston points out that most published accounts of the results of treatment of disseminated sclerosis are based on the degree of disability before and after treatment. In a previous report in which he and McAlpine analyzed 1,582 cases of disseminated sclerosis in 414 patients, it was found that 1,221 ended in a remission, leaving little or no increased disability. The end-results of individual episodes are, therefore, a poor criterion of effective treatment. Compston feels that in assessing the effect of medical treatment in disseminated sclerosis the essential criterion is the prevention of fresh relapses. Disability by itself is insufficient evidence. Though ideally an untreated control group should be used for comparison with a treated group, it has been found possible to analyze treated groups by comparing the relapse rate before and after treatment. The results in 57 patients treated by administration of artificial pyrexia and arsenic and in 33 receiving large doses of antihistamine drugs were analyzed. The only firm conclusion that can be drawn from this study is that the administration of artificial pyrexia followed by arsenic, or of arsenic alone, and the administration of antihistamine drugs in high doses, did not, during the limited period of follow-up, alter the relapse rate after treatment as compared with that before treatment. In both groups, however, the treatment was in many cases begun after the disease had been in existence for some years. In both groups the average duration of the disease before treatment began was between seven and eight years. Treatment of any sort must obviously have the highest chance of success if started early, because of the tendency for symptoms once established to progress. But in the small number of cases in which treatment was begun during the first year of the disease there was no difference in the relapse rate between the two groups. A standard method of assessing the degree of disability, during a follow-up of at least five years, is suggested.

Histological Diagnosis of Hepatitis in Childhood.—Perry calls attention to the difficulty that sometimes arises in determining the cause from the histological picture in children with liver disease. He defines hepatitis as a nonsuppurative process characterized by zonal necrosis and a cellular response predominantly of the nongranular type. The first two cases presented were in children with severe infectious hepatitis and the histological and clinical pictures were in agreement. The second case is noteworthy because it is likely that if the histological diagnosis is correct, this child almost certainly contracted the virus infection in utero. The third case is that of an infant who died soon after a premature delivery. Examination of the liver showed the histological appearance of nodular hyperplasia, indicating that the hepatitis had been progressing for some time in utero before precipitate delivery. However, diagnosis is rigidly histological, and in spite of the exclusion of syphilis and blood group incompatability it is devoid of proof. Two cases of galactose intolerance are mentioned in which the histological picture was that of chronic hepatitis. These demonstrate the flimsy structure of chronic hepatitis as a diagnosis, especially if it is too often reconciled with a virus etiology.

Punch Biopsy of Liver in Children.—Punch biopsy of the liver has become a valuable means of diagnosis of hepatic disease in children. The authors report their results in seven children, 1 to 14 years old. These children were given injections of vitamins C and K and barbiturates or opiates 24 hours before the intervention. After they had fasted for 12 hours, a Van-Silverman needle was inserted through a small incision into the 9th intercostal right space under local anesthesia. The procedure did not last more than eight seconds, and a 2 to 3 cm. specimen was easily obtained. The small lesion was not sutured but was protected with sterile gauze and an ice bag was placed on the area while the child was instructed to stay in bed for 12 hours. The histological specimens obtained were far superior to those the authors had obtained from other children by means of needle biopsy. The diagnosis of liver disease was confirmed in each child. There were no complications.

Liver Extract and Vitamin B_{12} in Children.—Liver extracts combined with vitamin B_{12} were used to treat 30 children with acute disease of the respiratory and cardiovascular apparatus. Atrophy, denutrition, asthenia, anorexia, and a pale color of the skin and mucous membranes were present in all these children. The disease had a tendency to become chronic despite the antibiotic, anti-infectious, and dietetic therapies that had been instituted. A first group of 15 infants, 3 to 15 months old, were given 1 gm. of liver extracts and 15 mcg. of vitamin B_{12} orally at breakfast every day for 20 to 25 days. The therapy was well tolerated, and there were no disturbances of the gastrointestinal apparatus. The infants gained appetite and weight. Their general condition improved, and the blood picture revealed an increased number of erythrocytes and higher levels of globulin and protein. Only a few of them, under six months of age, did not benefit from the therapy. The second group of 15 children, 2 to 15 years old, received 2 gm. of extracts of fresh liver and 15 mcg. of vitamin B_{12} intramuscularly every other day for 20 to 25 days. The injections were always painless and never caused allergic reactions. The cytochemical changes in the blood picture were superior to those obtained in the first group of patients. There was an increased number of reticulocytes and erythrocytes and higher levels of globulin and protein. The action of the two products was reciprocally enhanced. In fact, oral administration of vitamin B_{12} alone produces only an increase of appetite and, therefore, of weight, whereas when it is combined with liver extracts there is also a slow but progressive and beneficial modification of the blood picture.

Combined Anesthesia with Curare in Cesarean Section.—Comparison of the results in the 45 cases of cesarean section under combined anesthesia consisting of local anesthesia and intravenous administration of Narkotal (a solution containing 0.11 gm. of the sodium salt of isopropyl-beta-bromallyl-N-methyl barbituric acid, 0.1 gm. antipyrine, and 0.1 glycerin in water) with curare and nitrous oxide since late 1950 with those in 56 cases of cesarean section under ether anesthesia since late 1949 shows no certain difference with regard to fetal mortality ascribable to the anesthesia. With regard to the combined anesthesia, however, Bergquist and his associates note the following advantages: for the mother, rapid anesthetization with prompt recovery, reduced hemorrhage, and reduced postoperative distress; for the infant, little or no risk of asphyxia; and, for the obstetrician, smaller doses of the anesthetic agent, with excellent muscular relaxation, facilitating operation. The authors caution that the use of curare calls for a team skilled in anesthesiology.

"Early Diagnosis" in Cancer of Breast.—Kreyberg says the reason for the depressingly low results in complete recovery in mammary cancer is in the first place that the tumor cells may have spread beyond surgical control before operation is carried out, even before diagnosis is made, and/or in the second place that the tumor cells are not sufficiently radiosensitive. He analyzes the expression "early diagnosis" and examines the usefulness of various definitions of the term, mainly to clarify criteria for the immediate recognition of cancer of the breast at a time when complete recovery is possible if the patient receives the best possible treatment. One definition of "early diagnosis" commonly used is diagnosis of a tumor still in stage 1, when it can be completely removed by mastectomy. Another attempt at a productive definition of "early diagnosis" is diagnosis immediately after the first symptom, whatever its nature, but even when the length of time between diagnosis and treatment is reduced to a practical minimum only about half the patients can count on living free from symptoms for five years. A third definition is diagnosis of a very small tumor. The author points out that these three most usual definitions of "early diagnosis" fail, the first one because the criteria are available only as a result of retrospective clinical analysis, the second and third because there are no criteria that enable all patients to recognize the tumor at a stage when certain or practically certain recovery can be counted on with the best methods of treatment at hand today. He knows of no other definition that makes this possible. On diagnosis about two-thirds of the tumors have metastasized and are at a stage when half the patients will die of their tumors. The tumors differ in degree of malignancy. Grade 1 tumors, while malignant, have a moderate malignancy; they are relatively highly differentiated and grow and metastasize slowly. Grade 3 tumors are highly atypical and metastasize rapidly. Between the two extremes are grade 2 tumors. Differentiation between the two extreme groups is comparatively simple. The classification of the middle group is difficult and gives the greatest room for individual evaluation. For the tumors in group 1 a slightly earlier or slightly later diagnosis does not play an important part, as the tendency to metastasize is small. Tumors of grade 3 have often metastasized before they are recognizable by present methods of examination. In tumors of grade 2 the time factor is of essential significance. Statements to the effect that "with early diagnosis of cancer of the breast over 90 per cent are cured" depend on retrospective analysis of a treated material in which patients determined as having early cases are selected on the basis of knowledge not available until after the patients are operated on and treated. The possibility of recovery is around 50%, with a possible maximum of 60%. The inherent malignancy of the cancer is the most decisive factor. It is, however, the right and duty of every physician to take an optimistic view with regard to the individual patient, as cancer of the breast like many other diseases can bring happy surprises. Every one who has followed the treatment of mammary cancer will know of cases with favorable outcome in spite of a rather hopeless outlook at the start, with both highly atypical primary tumor and metastases.

*Causes of Premature Births and Causes of Deaths in Premature Infants. U. Rolfsen.—p. 994.
Pacifiers and Dental Caries. P. Selander and A. Syrrist.—p. 1003.
Myocarditis in Infants. R. Kostmann and M. Pehrson.—p. 1012.

Causes of Premature Birth and Causes of Death in Premature Infants.—From his analysis of 591 cases of premature birth at the Bergen Women's Clinic, Rolfsen concludes that premature birth may depend on the complications of pregnancy, maternal illness, and twin pregnancies and that there may also be a habitual or hereditary tendency toward premature delivery. Clinically demonstrable disease as the cause of death in premature infants seemed to account for about 20% of the cases; in 80% the cause of death was more or less uncertain. In cases with cephalic presentation and small fetuses short duration of labor tended to be harmful. In the first week of life there was a direct ratio between viability and weight. The death rate declined as the infants attained normal weight. After reaching normal weight the infants presented about the same mortality as full-term infants. Deficient development thus seems to be the main cause of death among premature infants. Mortality among premature infants should be combated by guarding against the factors responsible for early delivery. More thorough maternal control is necessary and more extensive hospitalization from the 28th week for diseases of pregnancy is desirable. The newborn premature infant requires special treatment by well-trained personnel.

Isoniazid (Isonicotinic Acid Hydrazid) in Leprosy.—Leprosy and tuberculosis are related diseases. Their causal agents are mycobacteria of similar morphological and staining characteristics. Normal persons who in the past had lived with patients with leprosy can be immunized against leprosy by the BCG vaccine. Sulfones and *p*-acetylaminobenzaldehyde thiosemicarbazone seem to be promising in the treatment of either disease. However, these drugs cannot be given for a long period of time, because of certain unfavorable effects and intolerance. On the basis of the good results of the administration of isoniazid in tuberculosis, the authors resorted to this drug in the treatment of 12 adult patients with leprosy. The patients had skin lesions either moderate or marked with histological characteristics of the type "L" or "Ind" of the disease. All were bacilliparous. The drug was given in daily doses of 100 mg. for 15 days after which the daily dose was fixed at 200 or 300 mg. administered in three fractional doses. This is a preliminary report with results obtained to date. The patients had had treatment for six or seven months and are still under treatment. The drug was well tolerated. The general condition of the patients and of the skin lesions was greatly improved. The clinical improvement was not associated with marked bacteriological changes. Diminution of the number of bacilli in smears of material taken from the skin or from the nasal mucosa and morphological changes of the bacilli were observed in rare cases only. The authors conclude that isoniazid is indicated in leprosy, especially in anemic persons with leprosy who had had sulfones or *p*-acetylaminobenzaldehyde thiosemicarbazone and cannot receive any more of these drugs because of intolerance or harmful effects of the drugs. They advise giving alternately sulfones, *p*-acetylaminobenzaldehyde thiosemicarbazone, and isoniazid.

Neoplastic Cells in Bone Marrow.—The types of cancer that most frequently produce bone marrow metastases in the form of neoplasic cells are cancer of the prostate, lung, and breast and the neuroblastomas. The author reports six cases. He emphasizes the value of the examination of material taken, by sternal puncture, from the bone marrow for the diagnosis of cancer. The finding of malignant cells in the bone marrow confirms the diagnosis of cancer. This type of metastasis indicates that there exist metastases in several other viscera that had not been observed by clinical or roentgen examination. When an operation is planned, this type of metastasis shows that the patient is beyond surgical intervention. Neoplasic cells in the bone marrow can be identified by their morphology. They are larger than normal. The structure and staining properties are different than those of normal cells. The nucleus is very large. The nucleus-cytoplasm index is increased. Frequently there is mitosis. The nucleoli are abnormal in number, size, form and staining character. The cytoplasm is either abundant or scanty, but always basophilic, frequently vacuolated, and sometimes with inclusions. There are pathological mitoses. In the cases reported by the author, the neoplasic cells in the bone marrow were abundant. Two of the patients had cancer of the lung, one of the lung and liver, and three of the prostate. The patients were observed in very advanced stages of cancer.

*Heparin in Treatment of Arteritis of Lower Limbs. M. Remy, P. Cadiot and C. Pernot.—p. 961.
*Fundic Gastrectomy. L. Leger and F. Kanoui.—p. 962.

Heparin in Treatment of Arteritis of Lower Limbs.—Excellent results were secured by intra-arterial injections of heparin in three patients with acute thromboses superimposed on chronic arteritis of the lower limbs; amputation, which had been considered inevitable in two of the patients, was averted. Heparin therapy in these cases proved so effective that it was tried in 15 patients with severe arteritis accompanied by trophic disorders and necrotic lesions. Marked regression of functional disturbances, with an increase in the local temperature and sometimes in the oscillometric index, was obtained in nine of these; three were not benefited, probably because the site of the obliteration was particularly disadvantageous; and in one who showed improvement after three injections, treatment unfortunately had to be abandoned. Intra-arterial injections, preferably into the femoral artery directly above the obstruction, are essential; they may be given alternately with intravenous injections in acute cases, but when the intravenous route alone is used, the drug is largely ineffective regardless of the dosage given. A total of from 400 to 500 mg. may be given daily at the outset in acute cases, with a gradual reduction in amount as improvement progresses. Treatment may be supplemented with procaine and procaine amide (Pronestyl) hydrochloride, also administered intra-arterially, when necessary. A single intra-arterial injection daily, without intravenous administration, is usually sufficient in less severe cases; from 8 to 12 injections of 100 mg. each may be given in such cases and the series can be repeated if necessary. The results obtained by the use of heparin are usually more pronounced, rapid, and lasting than those obtained by other methods.

Fundic Gastrectomy.—French and American surgeons, working independently, have proceeded along similar lines in their efforts to improve the surgical treatment of ulcerous disease by resecting as much of the acid-secreting area of the stomach as possible. The method developed by the authors removes the whole of the fundus and the vertical segment of the corpus contiguous to the greater curvature, leaving a gastric tube, not much larger than the esophagus, along the lesser curvature. The pyloric antrum, into which the tube opens, is left intact and pyloric functioning is preserved to the maximum because the vessels of the lesser curvature and its sympathetic nerve supply (the pneumogastric nerves) are respected. This procedure has been in use for several months, and its results will be reported as soon as the follow-up period warrants it. Investigation of the literature a posteriori showed that a similar method, proposed by Connell in 1929, was studied experimentally by him in 1951. Wangensteen's recently developed tubular gastrectomy resects the whole of the greater curvature but leaves the lesser curvature and the adjacent portion of the stomach intact; it is completed by a pyloroplasty. Arnous and Gibert advocate a partial resection of the fundus combined with a gastroenterostomy as a means of reducing hydrochloric acid-pepsin secretion, thus independently duplicating one of Wangensteen's earlier procedures. Postoperative determinations of gastric acidity show that most operations directed against ulcerous disease contribute to a reduction in acidity by permitting an intragastric reflux of alkaline secretions. Substantial reduction of acidity followed fundic gastrectomy in three of five patients operated on by the authors; in the fourth, the preoperative level was not significantly high; and in the fifth, whose hospital stay was prolonged by a postoperative pulmonary suppuration, repeated determinations showed gradually increasing acidity after an initial decline. Further study and a longer follow-up are needed to determine the definitive effect of this procedure on gastric acidity. Mediogastric stenosis, for which no explanation can be offered, sometimes occurs as an early postoperative complication of fundic gastrectomy, regardless of the method used.

Needle Biopsy of Kidney.—Needle biopsy of the kidney is a delicate procedure requiring skill and experience. It often furnishes valuable diagnostic information and may be used with safety in patients with various renal disorders. Transient macroscopic hematuria in two patients and signs of shock in a third were the only complications noted in a series of 55 renal biopsies; two patients had a slight rise in temperature the evening after the procedure, and four others had an accelerated pulse rate in the first two hours. Successful performance of the biopsy was followed by microscopically detectable hematuria during a 48 hour period showing that penetration of the kidney had been achieved. All patients were kept in bed for 24 hours after the biopsy and were given antibiotics and coagulant therapy for 48 hours. Renal biopsy may provide the solution to difficult diagnostic problems; in one of the authors' patients, a 40-year-old man with hematuria, a large right kidney, and moderately impaired function, biopsy eliminated the suspicion of cancer and established a diagnosis of hematuric nephritis. Histological study of biopsy specimens facilitates early diagnosis of renal tumors, especially cancer. Appropriate therapeutic measures can also be more easily instituted when the condition of the renal tissues has been accurately determined. Contraindications are numerous; needle biopsy of the kidney should not be attempted in the presence of renal or perirenal suppuration, hydronephrosis, and renal tuberculosis or even when the kidney is polycystic. The technical difficulties encountered in carrying out the procedure are greatly increased by the renal atrophy characteristic of certain conditions.

Local Applications of Hydrocortisone Acetate in Eczema and Pruritus.—Hydrocortisone acetate (Compound F) ointment in concentrations of 1 and 2.5% was used in treating 48 patients with various forms of eczema and pruritus. Hospitalized patients received daily application; all others were treated two or three times a week at the office. Patients with symmetrical lesions were selected for treatment whenever possible so that the effect of the hydrocortisone acetate ointment could be compared with that of the base or of an ointment whose action was already known, such as Dalibour ointment. Very little was needed to secure a clinical effect; 22 tubes of ointment containing 5 gm. each were enough for six weeks' treatment for all 48 patients. Light friction to increase absorption was used in applying the ointment, after which the surface was left either uncovered or protected by a fine gauze. Prompt and striking relief was obtained in cases of localized pruritus. Successive applications were followed by more prolonged periods of sedation, so that treatments could eventually be spaced at intervals of as much as four or five days without discomfort. Premature discontinuance of the treatment, however, was followed by renewed pruritus. The best effect was obtained with the 2.5% ointment. Certain chronic and refractory eczematous lesions were also greatly improved or cured; edema and oozing disappeared, and, after a period of desquamation, the skin recovered its normal smoothness, suppleness, and color. Improvement was usually noted within 48 hours, but treatment was continued for several weeks even after apparent cure because recurrence almost always followed if application of the ointment was discontinued too soon. Comparison of the control lesions and those treated with hydrocortisone ointment showed that, while the control lesions were sometimes benefited by the ointment base or the other preparations used, improvement in those treated with hydrocortisone acetate ointment was always greater and usually incomparably so. Tolerance for the ointment was uniformly good; it had no cosmetic disadvantages; and no contraindications to its use have yet been established.

*Trichomoniasis Vaginalis: Clinical, Bacteriological, and Anatomicopathological Study (Continuation and Conclusion). G. B. Candiani.—p. 301.

Treatment of Trichomoniasis Vaginalis.—Treatment of Trichomoniasis vaginalis has always aimed at a specific action on the Trichomonas and the other bacteria that often accompany this condition. However, since it is an altered biological state of the vagina that is favorable to the development of the flagellate, the specific treatment caused the Trichomonas to pass from a phase of pathogenicity to one of saprophytism with an almost asymptomatic picture which was erroneously interpreted as a period of temporary recovery. The treatment should first aim to restore the vagina to a normal biological state and then to influence the flagellate. In addition, since a previous study (*J. A. M. A.* **152:**287 [May 16] 1953) revealed that the pathogenicity of the flagellate is linked to a state of deficient estrogen secretion, the function of the gonads should always be investigated in patients with this infection, and hormone therapy should be instituted. Estrogens, mainly synthetic and of the stilbene series, should be administered, especially to patients with uterine hypoplasia and to those whose ovaries have been removed. The author's in vitro and in vivo studies revealed that thymol is effective on the protozoan but not on the vaginal flora. He, therefore, combined thymol with oxytetracycline (Terramycin) to potentiate the elective action of the former by sterilizing the coexisting flora. The new product was prepared in the shape of a small capsule, each capsule containing 5 cg. of thymol, 10,000 mg. of oxytetracycline, 10 drops of 1% procaine (to avoid a burning sensation when the capsule was applied) and gelatin. One capsule was introduced into the vagina of pregnant and nonpregnant women with this infection every evening for from three to eight evenings. The author obtained good results in 146 patients who were treated with this preparation and concurrent administration of small doses of synthetic estrogens. He secured an immediate recovery in all the patients. The flagellate and the symptoms disappeared in all. A follow-up one to three months later revealed a definitive recovery in 128 of the patients.

*Significance of Thrombocytes in Allergic Processes: I. Communication: Reduction in Number of Thrombocytes in Vivo After Exposure to Allergen. H. Storck, P. Bigliardi, H. Brenn and R. Hoigné.—p. 692.

Thrombocytes in Allergic Processes.—Using Feissly and Lüdin's technique, the number of thrombocytes in the peripheral blood of 449 patients and healthy control persons was counted with the phase microscope before and within half an hour, one hour, and one and a half hours after they had been given small doses of various drugs (one-fourth to one tablet by mouth or one-tenth to one-half of an ampul by injection). The maximum increase or reduction in the number of thrombocytes was expressed in percentage of the initial value. Of the 449 persons, 70 had a history of drug allergy, and their hypersensitiveness to the drug was manifested clinically by urticaria, eczema, rash, purpura, anemia, agranulocytosis, and symptoms of shock, which disappeared when the drug was discontinued and reappeared on repeated exposure to the drug. In these 70 persons, the number of the thrombocytes was, as a rule, reduced by 15% or more of the initial value within one and a half hours after the administration of the test dose of the drug. In the 379 persons who were not sensitive to the drugs tested, the number of the thrombocytes was increased, or as a rule there was less reduction. Occasional or repeated reduction in the number of thrombocytes occurred with a few drugs in persons without clinically demonstrated allergy. Statistical evaluation of the changes in the number of thrombocytes showed significant differences in that in the presence of drug allergy the mean values were found between −22% and −28%, while in the absence of hypersensitiveness to the drug the mean values were between +11% and −5%. Control counts of thrombocytes carried out in the morning on the empty stomach without exposure to the drug showed mean values of −1% in 204 persons and −5% after a nonallergenic test breakfast in 21. The behavior of the thrombocytes can, therefore, be used as a test for clarifying a possible drug allergy (thrombopenic index). When the results of the thrombocyte counts were compared with those of leukocyte and eosinophil counts, it appeared that the response of the thrombocytes was more pronounced and more specific than that of the leukocytes and eosinophils, and the same applies to the results of the thrombocyte reduction test as compared to those of cutaneous tests. In the individual case, sensitization is suggested with high probability by a pronounced reduction in the number of thrombocytes, but critical comparison with history and clinical symptoms always is necessary.

Hereditary Haemorrhagic Telangiectasia: Report of Bantu Case. A. M. Theron.—p. 557.

*Sporadic Cretinism in One of Fraternal Twins. T. James.—p. 562.

*Use of Noradrenaline in Acute Hypotensive States. M. B. Barlow, H. Ginsberg and J. Gottlich.—p. 564.

Sporadic Cretinism in One of Fraternal Twins.—The occurrence of sporadic cretinism is reported in only one of a pair of dizygotic twins. This condition is rare in multiple births; only four other comparable case reports were found by the author in the literature. The first case was published in 1914; 20 years passed before two more cases were published in one paper, and this was followed a year later by a fourth. The author's patient was a girl, while her twin was a boy. After the diagnosis of cretinism was made in the girl at the age of six months, ⅛ grain (8 mg.) of dried thyroid extract was given twice a day. The response to this treatment was gratifyingly rapid. After 28 days of treatment, the dose of the thyroid medication was increased to ⅛ grain given three times a day, and two months later to ¼ grain (15 mg.) twice a day. Comparable measurements of head, chest, abdomen, and length of the twins showed a striking approximation allowing for any expected differences that are usual between fraternal twins. At the age of 14 months, on a dose of ½ grain (30 mg.) of thyroid extract twice a day, the patient conducted herself in every way like a normal child. The degree of osseous developmental retardation in the hypothyroid twin reported on by the author was not assessed, and so the opportunity to determine whether the normal twin's thyroid hormone was adequate in utero for its defective twin's intrauterine metabolism and growth was missed. There is retrospective speculation whether the normal twin's thyroid gland was adequate for both, up to the time of birth when the defective twin would begin to develop its hypothyroidic state, and then it would be fair to say that the cretinism is congenital. The fundamental reason for sporadic cretinism in one of the author's pair of binovular twins could be either a genetic deficiency or that the inductive stimulus for the differentiation of the gland from its substrate was lacking or subliminal.

Use of *l*-Arterenol in Acute Hypotensive States.—A 4 cc. ampul of *l*-arterenol (Levophed) dissolved in 1,000 cc. of isotonic sodium chloride solution or dextrose in water was given by intravenous infusion to 21 surgical patients with acute hypotension. Five of the 21 patients were in such severe shock that any thought of operative interference was out of the question. On a *l*-arterenol infusion the condition of all these patients improved sufficiently for operation to be performed. All five patients survived for 12 hours. Two died after 12 hours from their original injuries, one died eight days later, and two survived. In nine patients acute hypotension occurred during the operative procedure. Three of these nine patients were given *l*-arterenol during the surgical intervention only, the other six received it during the postoperative period. All survived the operation, but two died subsequently because of their surgical condition. The remaining 7 of the 21 patients received *l*-arterenol as a treatment for acute hypotensive states not associated with anesthesia. In this group three patients died, two from pulmonary embolism and one from cardiac failure associated with severe toxemia. In these patients the blood pressure was well maintained by the *l*-arterenol until the time of death. Of the remaining four patients, one had severe burns and was in a hypotensive state for two days after injury despite adequate intravenous therapy. He was given *l*-arterenol for 24 hours, after which time his blood pressure was maintained at a satisfactory level. Two patients collapsed some days after surgical intervention and the cause of the collapse was not ascertained, but both recovered on *l*-arterenol infusions. In all patients with acute hypotension treated with *l*-arterenol the immediate results were dramatic. The blood pressure always rose within a few minutes after the institution of the drug. In this respect, the effect of *l*-arterenol was much more reliable than that of any other pressor drug. In addition it is less toxic. The authors caution against the administration of *l*-arterenol if the blood pressure cannot be continuously watched, for it may rise to dangerously high levels within a few minutes. Its use is thus only practicable where trained personnel are available day and night to take blood pressure readings and to adjust the infusion accordingly. Treatment with *l*-arterenol is purely symptomatic; therefore, its great use is in acute hypotensive conditions to raise the blood pressure until the cause of the sudden hypotension can be treated by blood transfusion or other appropriate measures.

BOOK REVIEWS

Emotional Factors in Skin Disease. By Eric Wittkower, M.D., and Brian Russell, M.D. With contributions from Peter Edgell, Desmond Irwin, and John Storach. Psychosomatic Medicine monograph. Forewords by Dr. R. M. B. MacKenna and Professor D. E. Cameron. Cloth. $4. Pp. 214. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

This timely book makes available to the medical profession an authoritative analysis of an important subject. It is unique in that it represents the joint endeavors of men trained in two different specialties, psychiatry and dermatology. The authors have performed an excellent job in collating and analyzing the case histories recorded in this volume and in attempting to correlate dermatological, pathological, and physiological data with the findings of the psychiatrists. At present many of the most fruitful lines of research in dermatology are those that can best be undertaken in the laboratory in order to combine chemical knowledge with scientific achievement. There is an overemphasis, however, on chemical and pathological findings as the keys to cutaneous etiological factors and diagnosis. Many of these laboratory findings are inappropriate and even misleading. The practitioner and the specialist must always bear in mind that the skin includes both soma and psyche, and the ills of the surface cannot always be healed unless the mind is relieved and the spirit emancipated. It must be emphasized at the same time, however, that proper local and systemic measures are still of primary importance in dermatological therapy.

This volume represents the combined efforts of five colleagues to point out that the skin stands between the person's inner and outer worlds and that a great interplay of forces is reflected in its functioning. The book consists of two parts, a general part dealing with the development of the skin, the function of the skin, and the neuroanatomy and physiology of the skin, and a second part dealing with specific disorders. A chapter on investigation and management of patients with skin diseases should aid the physician in handling certain cases. Although many important skin diseases with psychosomatic components have not been discussed, the omission is due to the fact that the authors' case material concerning these disorders was not large enough to draw conclusions that allow generalization. The diseases that are described are adequately presented and convincingly illustrated by selected case studies. Some of these patients obviously required deeper exploration from a psychoanalytic standpoint, but the presentation was suitable for this type of combined study.

This book can be read profitably, inasmuch as the authors have assembled a stimulating and significant series of interpretations of the complex changes that take place in the skin. It is a pioneer work that should stimulate both the dermatologists and the psychiatrists who will carry out future research in this field.

Man's Back. By Theodore A. Willis, M.D., F.A.C.S., Consulting Orthopedic Surgeon, U.S.P.H.S. Hospital, Cleveland. Cloth. $9.50. Pp. 161, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This monograph has resulted from the personal experiences of the author in dealing with lesions of the back. Because of the inaccessibility of the deeper parts to direct physical examinations and the complexity of the anatomic arrangements, differential diagnosis becomes quite a challenge. An attempt has been made to utilize not only the perfection of roentgenray technique but also the practical available knowledge of physiology and biochemistry. Enthusiasm for each new method of therapy has been properly restrained, yet worth-while associated material has been salvaged and included in the text. Chapter 1, dealing with embryology of the back, is particularly well written and stands out as an excellent example of detailed work presented in a simple, concise, and readable manner. A minor criticism might be raised in the discussion of gout on page 111, in which instance no mention is made of the newer drugs. It might have been better to have suggested a study of the serum uric acid rather than the time-honored, and often misleading, blood uric acid. The book is printed on good stock, and the roentgenograms have reproduced unusually well. Double column arrangement and a large-sized type are also advantageous features. This monograph can be recommended to anyone interested in the study of a patient with an aching back.

Clinical Investigation: A Manual for Practitioners and Students. By E. H. Stokes, M.D., Ch.M., F.R.A.C.P. With foreword by G. E. Beaumont, M.A., D.M., F.R.C.P., Physician to Middlesex Hospital. Cloth. £5/5/-. Pp. 628, with 345 illustrations. Angus & Robertson, Ltd., 89 Castlereagh St., Sydney, N.S.W., Australia; 48 Bloomsbury St., London, W.C.1, 1953.

Although the title "Clinical Investigation" suggests a guide for those involved in research at a clinical level, this is not the author's meaning. The book is rather what most physicians in America would call a textbook on physical diagnosis. As such it is interesting because of its profuse illustrations. In a sense this characterizes the book. It is particularly concerned with that part of physical diagnosis based on observation with the eyes. More mechanical techniques, such as percussion, are less extensively illustrated or described. The reader gains the impression that an experienced and canny observer has distilled long observation into a concise and sound summary. As such it presents a satisfactory text for a considerable part of physical diagnosis.

Arzneimittel-Synthese. Von Professor Dr. H. P. Kaufmann, Direktor des Instituts für Pharmazie und chemische Technologie der Universität Münster. Cloth. 87 marks. Pp. 834, with 26 illustrations. Springer-Verlag; Reichpietschufer 20, Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

This reference work provides a meeting ground for both the pharmaceutical chemist and the pharmacologist. The author, as did Frankel before him, has carefully blended information on the important steps of synthesis and structure-activity relationships among the members of the many groups of synthetic drugs now available. Thus the reader may comprehend the limitations imposed in drug manufacture on the types of derivatives that could be available and what alterations in pharmacological properties and side-effects might follow from a given modification of chemical structure. The author has had 30 years' experience teaching pharmacy students in German universities and has made numerous investigations in the field, especially in the study of neuropharmacological agents. Much emphasis is placed on this group of drugs, particularly on the synthesis and properties of the local anesthetics that have been derived from cocaine. The scope of the book may not fit in exactly with the interests of American pharmacologists. Although relatively little material on diuretics or drugs for cardiac patients is presented, a thorough discussion of vitamin and steroid synthesis and other topics from the German patent literature is provided. The book is divided into sections according to organ systems. Secondary classification is usually on a physiological basis, and detailed separation is made by chemical structure. This arrangement, though admittedly not ideal, makes the book easily usable by readers with either a chemical or a biological orientation. Each section is preceded by a short review of the physiology and anatomy of the system to be discussed. A list of significant European and American patents is provided. Both bibliography and index are detailed and well organized. A book that is of such value in integrating the work of pharmaceutical chemists and pharmacologists is a welcome addition to the literature of medicinal chemistry.

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

A Clinical Approach to Children's Rorschachs. By Florence Halpern, Ph.D., Assistant Professor of Clinical Psychology, New York University College of Medicine, New York. Cloth. $6. Pp. 270. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

In this book the author has attempted to communicate the insight she has gained, through her vast experience, in the interpretation of children's Rorschach test records. She has also made some significant contributions to a theory underlying the relationship between Rorschach test factors and developmental trends.

The book begins with a description of differences in test administration for the preschool and school age child and contrasts these with the procedure for adults. The author postulates three developmental levels that she feels are clearly delineated in children's Rorschach test records. These levels are 2½ to 4 years, 4½ to 6, and 6 to 10. The various test factors of area, determinants, content, etc., are discussed with regard to the manner and frequency in which they are manifested on each of these levels. Each of the 10 stimulus cards are then described in terms of the qualitative reactions that are characteristic of certain types of children as well as those considered normal for each of the developmental levels. The basic personality factors of self-concept, identification, anxiety, defense mechanisms, and ego strength are discussed in their theoretical aspects, and an attempt is made to show how their development and dynamic structure can be studied in children by means of the Rorschach test. The author has also tried to establish age patterns of characteristic Rorschach test responses that can be considered normal for each of the three developmental levels.

Most of the book is devoted to the means of detecting good adjustment, emotional disturbance, neurosis, schizophrenia, organic disorder, and mental retardation in children's records. Forty sample Rorschach test records are included to illustrate these categories. The scoring method used by the author appears to follow Klopfer, and her theoretical hypotheses and qualitative interpretations seem to be within the psychoanalytic framework. The book is intended for advanced students of the Rorschach test and practicing clinical psychologists. It is one of the best pieces of research that has been done in the area of child Rorschach interpretation, but it suffers from the lack of statistical and experimental data to corroborate the author's theoretical and clinical hypotheses. She does not state the exact way in which she arrived at her age patterns, but they are in general agreement with the norms established in the more objective studies like those of Ames and others. This is not the strong point of the book, however. Probably of greatest value to the clinician are the hypotheses offered for the clinical and developmental meaning of the various Rorschach test patterns and responses. But since this section is the most lacking in statistical and objective corroboration it is the part that must be most critically appraised by the individual reader.

The limitation of this study is recognized by the author herself, and thus she says that the inferences that are drawn concerning the meaning of certain responses and the significance of certain test factors must be considered as "working hypotheses." On the whole, the book is well written and should be of great interest to anyone concerned with the interpretation of the Rorschach tests of children.

Surgical Forum: Proceedings of the Forum Sessions, Thirty-Eighth Congress of the American College of Surgeons, New York City, September, 1952. Surgical Forum Committee: Owen H. Wangensteen, M.D., F.A.C.S., Chairman, and others. Cloth. $10. Pp. 716, with illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

This series of articles contains 129 excellent papers prepared by nearly 350 authors and represents the most recent studies and advances in surgical technique in this country and in Canada. There are 23 excellent articles on the stomach, esophagus, and intestines; 34 on the heart and blood circulation; many fine studies of water balance and electrolytes; and several articles each on plastic surgery, thermal injuries, cancer, shock, gynecology, obstetrics, and anesthesia. This volume represents the current results of the studies in basic medical sciences as related to surgery. The material contained in it extends our knowledge of the pathological physiology of disease. On it will depend much of our future therapy.

In many instances the articles that appear in the "Surgical Forum" make even the most modern textbook obsolete, for it is impossible for the standard textbook to keep abreast of all the new work that is being done constantly in these experimental fields. The book is well edited and printed in excellent type on good quality paper. It is liberally illustrated with photographs, drawings, and charts. It is exceptionally well indexed. This book should be valuable for every surgeon, and, certainly, no surgical resident should be without it.

Aviation Toxicology: An Introduction to the Subject and a Handbook of Data. Prepared under direction of Committee on Aviation Toxicology, Aero Medical Association. Cloth. $4. Pp. 120, with illustrations. Blakiston Company (division of Doubleday & Company, Inc.), 575 Madison Ave., New York 22, 1953.

This book should be most useful to aviators. Known facts are used to show how intoxications may occur from exposure to substances used in the aviation industry. General problems of aviation toxicology are discussed. Various classes of substances used in aviation are enumerated, and their possible hazards indicated. Methods are given of calculating the concentrations that may be injurious to persons in a plane. The pesticides have received considerable attention, because planes coming from tropical areas must be sprayed to destroy possible carriers of tropical diseases; for example, the tsetse fly, vector of African sleeping sickness, has been carried from Central Africa into the Union of South Africa spreading the disease. The use of the airplane in aerial crop dusting and also in reclaiming large areas of infested lands is discussed. The last chapter lists compounds and such information as their physical constants and maximum safe concentrations.

Endocrinology in Clinical Practice. Edited by Gilbert S. Gordan, M.D., Ph.D., Assistant Professor of Medicine, University of California School of Medicine, San Francisco, and H. Lisser, M.D., Clinical Professor of Medicine and Endocrinology, University of California School of Medicine. Cloth. $10.50. Pp. 407, with 90 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1953.

This series of lectures constituted a postgraduate course in clinical endocrinology and metabolic diseases. The subject matter conforms to that included in the usual textbook, with chapters on obesity and leanness, infertility, the endocrine therapy of neoplastic diseases, an appendix listing useful endocrine preparations, and trade names and doses. Since this is a compilation, it is not surprising to find a disproportionate amount of space devoted to some subjects; for example, nine pages are devoted to Paget's disease, a nonendocrine disorder, but no mention is made of chromaffin cell tumors. In general, however, the subject matter is covered well and conforms to the opinions held generally by the profession. One might object to the designation "juvenile myxedema" applied to a patient, aged 26, suffering from mild hypothyroidism, or to the statement that "osteoporosis characteristically responds dramatically to the administration of estrogens or of androgens." As stated by the editors, "this book is not intended for the medical student, nor for the research investigator, nor for the clinical endocrinologist, who would find little within these pages with which he was not already familiar." Others will find in it a well-written, well-illustrated résumé of clinical endocrinology as presented by a group of endocrinologists, surgeons, and other specialists dealing with endocrine disorders in a large university hospital. For these the book may be recommended.

Estudios de neurología clínica. Por L. Barraquer Ferré, director de la Escuela de neurología del Hospital de la Santa Cruz y San Pablo, Barcelona. Cloth. Pp. 770, with 225 illustrations. José Janés, Editor, Muntaner, 316, Barcelona, 1952.

This volume describes all neurological syndromes in detail, illustrating them with short case histories. The diagnosis, treatment, and prognosis are discussed. The photographs are excellent, the index is adequate, and the text is written in a clear and concise manner.

The Physician in Atomic Defense: Atomic Principles, Biologic Reaction and Organization for Medical Defense. By Thad P. Sears, M.D., F.A.C.P., Associate Clinical Professor of Medicine, University of Colorado School of Medicine, Denver. With foreword by James J. Waring, M.D., M.A.C.P., Professor of Medicine, University of Colorado School of Medicine. Cloth. $6. Pp. 308, with 53 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1953.

Dr. Sears has been associated for the past several years with civil defense and disaster planning in Colorado. Dr. Waring in his foreword states, "This book is the result of deep-seated conviction on the part of Dr. Sears that the community in which he lived should be prepared for atomic warfare." The stated objective of this volume is "first, to review briefly the present physical concepts of matter, gaining in this approach and without recourse to mathematical formulas, a sounder understanding of radioactivity and its applications. Attention will next be given the structure of the atom; the significance of radioactivity; the chain reaction and the atomic bomb; the use of isotopes. Then the symptomatology, pathology and treatment of atomic bomb injuries and the methods of civil defense will be reviewed." Section 1 is devoted to "Atomic Theory, Basic Physics and Atom Bombs." The presentation should be clear even to those lacking extensive training in biophysics or nucleonics. Section 2 deals with "Clinical, Biologic and Therapeutic Aspects of Atomic Warfare." More emphasis should have been given to the details of the management of casualties resulting from the blast and burn effects of an atomic explosion. The first aid and later treatment of burns in large numbers would present a major problem in the event of such an attack.

"Organization of the Medical Department for Atomic Defense," section 3, outlines many of the problems to be faced in planning for, or handling, a civil defense emergency. The author's estimates of casualties have been recently revised upward because of the production of more powerful atomic weapons. This will necessitate a revision of plans for the care and treatment of casualties. Many of the public health problems to be anticipated in the event of an atomic explosion are touched on but not in sufficient detail to serve as a complete guide for public health physicians having to contend with them.

At the end of most chapters there is a bibliography, which, for the most part, covers material up to and through 1951. An obvious disadvantage noted was the failure to indicate in the text where the items in the bibliography were used. The selection of material for illustration and the reproduction is quite good. The format is good and the type clear and easy to read. This book should serve as excellent supplemental reading for those interested in civil defense medicine.

Fundamentals of Disease: A Textbook of Pathology and Clinical Pathology for Nurses. By Emmerich von Haam, M.D., Professor of Pathology and Director of Laboratories, Health Center, Ohio State University, Columbus. Cloth. $4.75. Pp. 424, with 90 illustrations. Springer Publishing Co., Inc., 1 Madison Ave., New York 10, 1953.

Believing that the increased responsibilities placed by modern medicine on the nurse demand that she have a better understanding of the disease processes encountered in her patients, the author has described the lesions that underlie these processes. The first part is devoted to a discussion of the six principal lesions: degenerative changes, circulatory disturbances, inflammation, adaptive changes, tumors, and cellular death. The second part presents the reactions caused by various injurious physical and chemical agents. The third part deals with the diseases of the individual organ systems. The special pathology is followed in each instance by brief descriptions of laboratory tests and their relation to nursing functions. This close correlation between structural changes and pathological laboratory findings is intended to help the nurse understand why certain tests are ordered by the physician for his patient. The responsibilities of the nurse in collecting and handling specimens, as well as special care of the patient, are stressed. The illustrations in this book have been chosen from specimens and patients personally observed at the author's institution. Study questions follow each chapter. Teachers will find this book a valuable aid to instruction. The subject matter is well-organized, clear, and interesting.

Chronic Pulmonary Emphysema: Physiopathology and Treatment. By Maurice S. Segal, M.D., Clinical Professor of Medicine, Tufts College Medical School, Boston, and M. J. Dulfano, M.D. Modern Medical Monographs, 8. Cloth. $5.50. Pp. 180, with 32 illustrations. Grune & Stratton, Inc., 381 Fourth Avenue, New York 16, 1953.

Various aspects of hypertrophic pulmonary emphysema are reviewed in this monograph. The material on pulmonary function tests is well presented. The pathophysiology of the disease is, for the most part, clearly described, including recent studies on intracardiac pressures in cor pulmonale as well a briefer mention of the forces responsible for retarded expiratory air flow. The chemical effects of oxygen treatment are not adequately reviewed, however, especially in respect to adaptive changes that follow oxygen inhalation. Retention of carbon dioxide in the blood and alveolar air is emphasized as the danger of oxygen treatment, and hyperventilation by mechanical means is properly advocated in cases of uncompensated respiratory acidosis. In the original studies on oxygen therapy in pulmonary and cardiac failure, however, it was pointed out that an increased arterial carbon dioxide tension was responsible for high carbon dioxide elimination per unit volume of ventilation; the increased carbon dioxide concentration in the alveolar and expired air is itself part of the mechanism that makes possible the continuous use of oxygen and, consequently, of clinical benefit. An elevated arterial carbon dioxide tension is more advantageously lowered by therapeutic measures that improve respiratory function, since, in the absence of an acid shift in blood pH, increasing the ventilation by artificial respiration devices may upset a useful adaptive response.

The therapeutic section includes a diverse discussion of symptomatic treatment, administration of antibiotic aerosols, corticotropin (ACTH) and cortisone, oxygen, mechanical respiration, pneumoperitoneum, psychotherapy, and breathing exercises. Although some of the procedures advocated still have to bear the test of critical judgment, many valuable hints for the management of patients with pulmonary emphysema will be found in these chapters. The book is readable, adequately illustrated, and should be helpful to the practitioner or student of medicine interested in diseases of the chest.

Fibrocystic Disease of the Pancreas: A Congenital Disorder of Mucus Production—Mucosis. Edited by Martin Bodian, M.D., Director of Department of Morbid Anatomy, Hospital for Sick Children, London. Contributors: Martin Bodian, in collaboration with A. P. Norman, M.D., M.R.C.P., Deputy Director, Institute of Child Health, London, and C. O. Carter, B.M., M.R.C.P. Cloth. $9.50. Pp. 244, with 133 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; [William Heinemann, Ltd., 99 Great Russell St., London, W.C.1], 1953.

This monograph brings together for the first time in book form the clinical, genetic, and pathological information relating to the disease usually labeled cystic fibrosis or fibrocystic disease of the pancreas. It consists of a survey of the literature pertinent to outlining the evolution of concepts of pathogenesis of the disease and a clinical and pathological review of the group of patients studied. A review of the varied clinical manifestations of the disease is based on analysis of 116 cases. The genetic aspects of the disorder are presented in a separate chapter, and the recessive gene hypothesis of etiology is accepted on the basis of analysis of the familial incidence.

The most important feature of the book is the section on pathology. This section consists of a system by system description of the gross and microscopic pathology observed in 62 patients who came to autopsy. It is profusely illustrated by photographs remarkable for clarity of detail and excellence of reproduction. Special emphasis is given to illustration, by photomicrograph, of the pathology of mucous glands throughout the body and the abnormalities of the pancreas and respiratory system that are the basis for the clinical manifestations of the disease. The thesis expressed in the subtitle, "A Congenital Disorder of Mucus Production," is well substantiated by the material presented. The clinical and pathological protocols of the 116 cases studied are included. A chapter that describes other pancreatic dysplasias simulating some of the manifestations of fibrocystic disease of the pancreas, is included, and the contrasting pathology of congenital hypoplasia of the exocrine pancreas and congenital cystosis of the pancreas is described and illustrated. The intent of the monograph, to present the clinical and pathological aspects of fibrocystic disease of the pancreas, has been accomplished with a clarity not compromised by the meticulous detailed observations, and with the liberal use of superior illustrative material. The book carefully documents the concepts of the author concerning the pathological unity of the manifestations of the disease. It is stimulating for those in a position to undertake research in new or better forms of therapy for this lethal disease and is unusually rewarding for the physician responsible for the care of patients with fibrocystic disease of the pancreas.

Modern Concepts of Communicable Disease. By Morris Greenberg, M.D., M.S.P.H., Director, Bureau of Preventable Diseases, New York City Department of Health, and Anna V. Matz, R.N., M.A., Public Health Nursing Consultant in Communicable Diseases, New York City Department of Health. Foreword by Harry S. Mustard, M.D., LL.D. Cloth. $6.20. Pp. 553, with 15 illustrations. G. P. Putnam's Sons, 210 Madison Ave., New York 16, 1953.

This volume is designed for physicians and nurses and as a textbook. The authors have attempted to present a compact and condensed summary of diagnostic, therapeutic, nursing, and preventive measures. The first part of the volume deals with general principles of infection, treatment, and nursing care. In the latter the authors have sought to simplify procedures and to remove many of the unnecessary details that have made home care so difficult. Most readers will welcome their attempted simplification and their liberal point of view, but will question the statements that sterilization is "synonymous with disinfection" (page 84), that pasteurization is a means of sterilizing milk (page 86), or that typhus is caused by a virus (page 11). The second section deals with about 60 diseases grouped according to principal modes of transmission. Each disease is discussed according to a standard pattern—the causative agent, the host, the environment, and medical care. The approach is modern and orderly, and the discussion clear and constructive. The reader may wonder, however, whether a more thorough discussion of fewer diseases might be preferable to the attempt to say something about so many.

The references at the ends of the chapters need extensive revision. Many are inaccurate, as, for example, the reference to Zinsser's classic on typhus, "Rats, Lice and History" as a book on bubonic plague under the title of "Plague, Rats and History." There is a list of 36 references to articles on rickettsial diseases as contrasted to only 6 on typhoid and none on meningococcic infections. The volume has much to commend it but requires more careful editing. These many imperfections, which mar the volume and are evident to the critical reader, should not obscure the fact that the authors have prepared a highly useful text that is of special value to physicians caring for communicable disease in the home.

Pulmonary Tuberculosis: A Handbook for Students and Practitioners. By R. Y. Keers, M.D., F.R.C.P., F.R.F.P.S., Medical Director, Red Cross Sanatoria of Scotland, Tor-na-Dee, Milltimber, Aberdeenshire, and B. G. Rigden, M.R.C.S., L.R.C.P., Physician, Lewes Chest Clinic. With new foreword by F. H. Young, O.B.E., M.D., F.R.C.P., Physician, Brompton Hospital for Consumption and Diseases of Chest, Brompton, England. Third edition. Cloth. $5.50. Pp. 324, with 150 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2; E. & S. Livingstone, Ltd., 16 & 17 Teviot Place, Edinburgh 1, 1953.

This handbook, primarily for the student and practitioner, makes no claim for originality of method or material but aims to stimulate sufficient interest in a fascinating subject to encourage further pursuit in postgraduate years. The practitioner may obtain from it an outline of present-day therapeutic measures. More specialized details are omitted. Much of what was taught in 1946 is out of date, and this edition is almost entirely rewritten, with a new section on management of the minimal lesion. Many of the skiagrams are new. The size remains much the same because of condensation and elimination of surgical details to produce a volume convenient to handle. The authors help the student to see pulmonary tuberculosis in good perspective so that he does not get lost in a maze of detail. Although the laboratory phases are a little encumbered by the inclusion of a few obsolete and meaningless features, such as the now outmoded Gaffky system of enumerating bacilli in the sputum, the clinical chapters in the authors' own fields of observation and experience are well presented, and the illustrations are pointed. It is also encouraging that the authors have not overaccentuated the modern and note that "the recipe for success remains unaltered and depends as before on the intensity and breadth of our vigilance against the disease and upon the vigour and completeness of our efforts"—a laudable stand, particularly as conveyed to the student and practitioner who at this time may otherwise belittle the continued importance of an intricate disease.

Physiology of Muscular Activity. Originally by Edward C. Schneider, M.P.E., Ph.D., D.Sc. Fourth edition, by Peter V. Karpovich, M.P.E., M.D., Professor of Physiology, Springfield College, Springfield, Mass. Cloth. $4.75. Pp. 340, with 77 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

The fourth edition of this book is as valuable and attractive as the first. Despite the addition of important recent material, the size has been kept within bounds. Assuming that the student has had introductory courses in anatomy and physiology, the author discusses muscular activity from the standpoint of muscular structure, nervous control, fuel required, the role of oxygen, energetics, relative energy costs of different activities, respiration, composition of the blood, cardiac output, pulse rate, blood pressure, coordination, fatigue and staleness, external temperature, fitness and age, tests of fitness, body types and posture, activity during convalescence, and ergogenic aids (special foods, drugs, and training ideas) in work and sports. The bibliography includes foreign publications, and a judicious use of references enables the author to condense his text without lapsing into dogmatism.

The section on types of physique reflects an unsatisfactory state of that subject; there is reason to doubt that it has been much advanced by Sheldon's polysyllabic terminology and mathematical devices. The section on ergogenic aids contains some extraordinary illustrations of means that have been used, rightly or wrongly, to increase work output, from cardiac stimulants for mountain climbers to phosphates for coal miners. These ideas are dispassionately appraised, and the book should go far to discourage some irrational fads. The wealth of personal experience of the present author and his predecessor is implicit throughout the text, and the practical applications on every page make it interesting. The book is of fundamental importance to every physician related in any way to schools and athletic programs.

Shoulder Lesions. By H. F. Moseley, M.A., D.M., M.Ch., Assistant Professor of Surgery, McGill University, Montreal. Second edition. Cloth. $12. Pp. 329, with 216 illustrations and 43 colored plates by Helen MacArthur, B.A. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

The first edition of this book by H. F. Moseley was so impressive that it did not appear that anything of importance was missing. This second edition, however, is definitely an improvement, and it includes two new chapters: "Fractures of the Shoulder Region," and "The Clavicular Articulations."

The use of hydrocortisone and corticotropin (ACTH) in the treatment of arthritis and bursitis in the region of the shoulder has been accurately described and will be of real help to the physician who is frequently faced with the problem of these often refractory conditions. No chapter will be of greater help to the physician than that edited by Francis L. McNaughton, entitled "Neurological Aspects of Shoulder Pain." X-ray diagnosis and treatment is also discussed in a separate chapter by specialists eminently qualified to speak on these subjects, Dr. Carleton Peirce and Dr. Jean Bouchard, of McGill University.

The excellence of the printing and the reproduction of illustrations, including many in full color, drawn and painted by artist Helen MacArthur, are especially noteworthy. This excellent book no longer can be considered merely as a textbook but must be classed as a reference book. A copy should be in the library of every orthopedic surgeon, every surgeon of trauma, and of all physicians who have a scholarly interest in medicine and surgery.

The Low Sodium Cook Book: How to Prepare Tasteful Meals for the Low Sodium or Low Salt Diet—Including Suggestions for the Low Sodium, Low Fat, Low Cholesterol Diet. By Alma Smith Payne, M.A., and Dorothy Callahan, B.S., Research Dietitian, Massachusetts General Hospital, Boston. With introduction by Francis L. Chamberlain, M.D., M.Sc.D. Cloth. $4. Pp. 477. Little, Brown & Company, 34 Beacon St., Boston 6, 1953.

Physicians who prescribe low sodium diets and patients who must follow them will find this book invaluable. It is accurate, easy to read, and practical. It contains many suggestions, including intriguing recipes, that should greatly assist in making the low sodium diet more palatable. The importance of the physician's instructions and guidance are stressed throughout the book. The 18 chapters deal with the various classes of foods, methods of preparation, seasonings, foods to avoid, the packaged lunch, and a discussion of what to eat outside the home. The sodium content of individual servings and recipes is always indicated. A chapter on the low sodium, low fat, low cholesterol diet is included. In the appendix, the sodium, cholesterol, and fat content of common foods, the sodium content of public water supplies, and commercial low sodium products and concerns manufacturing them are listed. This book is recommended highly to physicians, patients, and dietitians as a guide for planning interesting, low sodium diets.

Rose and Carless' Manual of Surgery for Students and Practitioners. By Sir Cecil Wakeley, Bt., K.B.E., C.B., President of Royal College of Surgeons of England, London. Contributors: S. G. Clayton, M.S., F.R.C.S., F.R.C.O.G., Obstetrical and Gynaecological Surgeon, King's College Hospital, London, et al. Eighteenth edition. Cloth. $12. Pp. 1471, with 1011 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1952.

Presumably this manual is intended as a textbook and as a reference book for general practitioners. To fulfill this role it should contain full discussions of surgical fundamentals and of common surgical conditions, together with authoritative, up-to-the-minute résumés of less frequently encountered problems. In neither of these fields does the book achieve consistent success.

The chapters on infection, shock, and hemorrhage and blood transfusion are all of high quality, and there is a particularly good chapter on burns by Wallace. The chapter on biopsy in surgery is a new departure and deserves mention. Although parts of the rest of the book achieve the standard of those mentioned, others are less commendable. In part this may be due to delay between writing and publication, and it is disappointing to find so many recent advances omitted from a text dated 1952. For example, the chapter on water and salt deficiency, competent as far as it goes, is strangely uninformative about blood chemistry studies, and potassium is only mentioned briefly in an addendum (page 57). The only liver function tests mentioned (page 1022) are the levulose tolerance test and the urinary nitrogen coefficient; hepatic function is passed over with the statement "there is no satisfactory clinical or laboratory test of the efficiency of the liver." Diaphragmatic hernia is given one brief paragraph, and hiatus hernia is not mentioned at all, except for a note on the congenital short esophageal type in the section on diseases of the esophagus. Resection therapy for pulmonary tuberculosis is not even mentioned. Although Hirschsprung's disease is discussed in two different sections of the book, the space given to it is largely wasted, because modern concepts of the cause and treatment introduced by Swenson are not included. In the section on vascular surgery, the only method given for bridging arterial defects is the "saphenous vein graft supported by a vitallium tube if available" (page 139), and the classical ligations of major arteries are listed in the old-fashioned textbook way without any indications of the results of these ligations (page 149). There is no indication of the importance of the postphlebitic factor in the pathogenesis of "varicose ulcers."

There is one dangerous misconception that is not excusable on the basis of too recent advance. The fiction that a carcinoma of the breast can be "easily distinguished" clinically from an adenoma is perpetuated (page 889), and the pathetic list of signs of incurable cancer is cited under the heading of "diagnosis." The subsequent qualification that any suspicious lump should be regarded as cancer until proved otherwise is insufficiently stressed in view of the fact that this book is aimed at students on whom the future responsibility for early cancer diagnosis will rest.

The book is well printed and profusely illustrated. It is enlivened by an occasional misprint, as when the reader is informed that inoperable cancer of the bladder can be treated by radon seeds inserted through a "suprapublic" opening. Reference lists have been omitted, doubtlessly for economy of space, but in a modern textbook this is surely false economy.

In spite of its deficiencies, this manual remains one of the standard textbooks of surgery. The fact that it has gone through 18 revisions in over half a century is good indication of its general usefulness. Most of the deficiencies probably stem from the inevitable lag period that exists between the preparation and publication of such a comprehensive textbook. Some, however, are apparently due to a much too conservative attitude in accepting new developments in surgery.

Glaucoma: Pathology and Therapy. By Paul Weinstein, M.D., Associate Professor of Medical Ophthalmology, at University at Budapest. Translated by Julius Foldes, M.D., Director of Laboratories, Hazelton State Hospital and St. Joseph's Hospital, Hazleton, Pa. Cloth. $8. Pp. 295, with 36 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

By his painstaking research and careful selection of the world's literature on glaucoma, the author has provided a résumé of a problem that still baffles the ophthalmologist. He points out that the water balance, the water-binding capacity of the blood proteins (oncotic pressure), and the daily changes of ocular tension are greatly influenced by the hypophysis. He gives an excellent discussion on the sinus venosus sclerae (aqueous veins), the glass rod phenomenon, the laminary veins, the plexus ciliaris (Kiss), and of the cystic emissarium (of Weinstein) and episcleral emissary veins, and concludes that "Kiss-Weinstein's emissaria play an essential role in the discharge of aqueous humor, and, in cases of simple glaucoma, their activity supersedes that of the aqueous veins." The author is convinced that, in those patients in whom a spontaneous pulsation of the retinal veins is present, the vision has been preserved. The presence of spontaneous pulsation of the retinal veins, therefore, improves the prognosis of glaucoma.

The text includes Barkan's classification of glaucoma, pathological-anatomic characteristics, clinical characteristics, and operation of choice. Under therapy, the author advocates, in addition to the usual therapeutic regimen in glaucoma, specific therapy such as the use of vasodilators for the improvement of retinal circulation. He also recommends this for the improvement of retinal circulation in chronic glaucoma. He points out that high blood pressure with some retinal pulsation is of prognostic import, because under these conditions the venous retinal circulation is at its best. When the blood pressure is low and there is no spontaneous retinal venous pulsation, vasodilators in conjunction with drugs that raise the blood pressure are used. For the lowering of venous pressure, intravenously administered hypertonic solutions (salt, glucose) are recommended. Any student of glaucoma will want to include in his personal library this concise, compact monograph, which places the world's literature at his fingertips.

The Social Insects. By O. W. Richards, M.A., D.Sc. Cloth. $4.75. Pp. 219, with 63 illustrations. Philosophical Library, Inc., 15 E. 40th St., New York 16; Macdonald & Co., Ltd., 16 Maddox St., London, W.C.1, 1953.

The author, one of Britain's foremost entomologists, has written a very readable account of the communal activities of bees, wasps, ants, and termites. The results of the most recent research in this field are described clearly and authoritatively to establish for the reader the contrast between insect and human societies. Although human behavior depends almost entirely on learning in early life, insect behavior is unlearned, "unintelligent," and rigid. Despite such a limitation, it is surprising to learn how insects have developed societies of diverse complexities.

Medicine. Volumes I and II. Edited by Hugh G. Garland, T.D., M.D., F.R.C.P., Physician in Charge, Department of Neurology, General Infirmary at Leeds, England, and William Phillips, M.D., B.Sc., F.R.C.P., Senior Physician and Physician in Charge of Cardiac Department, Cardiff Royal Infirmary, Cardiff. Foreword by F. A. E. Crew, T.D., M.D., D.Sc., Professor of Public Health, University of Edinburgh, Edinburgh. Cloth. $25 per set. Pp. 1077; 1078-2146, with illustrations. St. Martin's Press, 103 Park Ave., New York 17, 1953.

The editors of this book believe that the advances in medical knowledge in the last half century are too great to be comprehended by any one person. Consequently, any text that is to present the knowledge, experience, and wisdom of the present generation must be the joint effort of many workers. The present volumes include contributions from 40 distinguished specialists in the medical schools of Great Britain and Ireland, one from New Zealand, and one from Canada. Furthermore, as Professor Crew points out in the foreword, the essential humanism of medicine has not become adjusted with the ever-expanding science of medicine. The concept of a unifactorial causation of disease is no longer satisfactory. Disease causation has become multifactorial through expanding knowledge in such fields as genetics, developmental physiology, nutrition, psychiatry, and sociology. These changes have made manifest that both society as a whole and the profession of medicine need a clear restatement of the purpose and objectives of medicine. The practice of medicine, as well as the teaching, must remain incomplete unless medicine concerns itself not only with the cure and prevention of disease in the individual and in the group but also with the problems that are created by the personal and social consequences of such disease.

Almost half of the first volume is devoted to subjects not covered in most texts of medicine, such as assessment of physical and mental health, natural history of disease, social aspects of the etiology of disease, genetic factors in disease, psychosomatic medicine, and rehabilitation. A chapter on the patient as a person presents abstracts of psychiatric interviews of both adult and child, and points out in brief paragraphs the uses of psychological testing, intelligence tests, and personality assessment. A section on nutrition and disease discusses the relation of poverty, pregnancy, growth, dental health, and physical fitness to the development of disease. The remainder of the first volume includes sections on infection and immunity, neoplasms, principles of diagnosis in adults and in children, the place of radiology in diagnosis, laboratory methods, general principles of treatment, symptomatic treatment, the skin in general medicine, common fevers, tropical diseases, effect of physical agents, diseases principally encountered in industry, and aviation medicine.

The second volume contains sections on the description of systemic diseases, such as diseases of the digestive system and the cardiovascular system. The arrangement is not on an etiological basis in contrast to the usual plan of American texts. Thus measles and whooping cough are described in a chapter on acute respiratory infections in the section on common fevers, while the common cold and influenza are included in diseases of the respiratory tract. Meningococcic meningitis, poliomyelitis, tetanus, herpes zoster, rabies, and lead encephalopathy are grouped under infections and intoxications of the central nervous system. Kala-azar and amebiasis are found in the section on tropical diseases. The text is well written and exhibits a more conservative attitude than is usual in this country. Thus, the relation of rheumatic fever to a preceding streptococcic infection is suggested, but not accepted, and, while neostigmine is recommended for myasthenia gravis, any involvement of the acetylcholine-cholinesterase system is not mentioned. The volumes are long for a textbook and the sections lack the completeness desired in a reference book. They make valuable collateral reading, however, and contain much information not collected in most other medical texts. A few references are provided in some sections but more would be desirable. The index is complete, and the reproductions of roentgenograms are superior.

The Nature of Virus Multiplication: Second Symposium of the Society for General Microbiology Held at Oxford University, April 1952. [Edited by Paul Fildes and W. E. van Heyningen.] Half-cloth. Pp. 320, with illustrations. Cambridge University Press, Bentley House, 200 Euston Rd., London, N.W.1; 32 E. 57th St., New York 22, 1953.

This volume contains the papers and the discussions of the symposium. The papers were not read during the meeting but were previously circulated in galley form to those expecting to attend. The symposium consisted essentially of discussions of these papers by the authors, invited speakers, and the audience as a whole, who thus had an opportunity to consider carefully the material in advance. Certain of the discussions are, therefore, of unusual value to the reader in helping to evaluate the complex array of data and theory presented by 18 capable investigators of the fundamental but still highly obscure and controversial problem of virus multiplication. No doubt the present status of this problem led the conveners of the symposium to select it for consideration in order to summarize the numerous facts defined by recent research and the current hypotheses that seek to fit these facts into a unified conception of the manner in which viruses are reproduced. This objective has been admirably attained, and the qualified reader will gain a comprehensive view of the contemporary knowledge and the best thought on this subject. The first paper deals with modern theories concerning the synthesis of proteins and nucleoproteins in general. The synthesis of viral proteins and nucleoproteins is then discussed with particular reference to some of the plant viruses, and it is suggested that the same cellular mechanisms that are concerned with normal protein and nucleoprotein synthesis are involved in the production of virus, the latter serving only to direct these mechanisms into the somewhat peculiar activities.

The remainder of the book concerns multiplication as observed in bacteriophages, certain mammalian viruses, and in those infecting insects. The essential similarities between the reproductive phenomena in each of these groups are thus given emphasis. To most of the authors these phenomena seem to support the prevailing concept of viral multiplication: the virus, in some as yet undefined manner, acts as a "stimulant" or "template" in a synthetic process whereby its own reproduction is accomplished and that involves in whole or in part the enzymes of the cell. Two older views find only occasional defenders. Indeed, the idea, once shared by many, that the virus simply activates a precursor that is a normal constituent of the cell somewhat in the manner that pepsinogen is converted to pepsin, is supported by a single investigator. In its simplest expression, the conception of virus as a minute, obligate, intracellular parasite, multiplying by binary fission, has been completely abandoned, although it is retained in a more complex form set forth in one excellent paper.

The book will represent a valuable addition to the virologist's library and should be of much interest to the biochemist and to others professionally concerned with the problem of growth. The format, typography, illustrations, and figures are excellent, as is likely to be the case with English scientific publications in general.

Human Neuroanatomy. By Oliver S. Strong and Adolph Elwyn, Associate Professor of Neuroanatomy, College of Physicians and Surgeons, Columbia University, New York. Third edition. Cloth. $7.50. Pp. 481, with 357 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1953.

Since the second edition of this book (1948), there has been a great advance in our knowledge of neuroanatomy and neurophysiology. The present editor of this volume has revised the text to conform to the more recent accessions in these fields. Many sections of the book have been largely rewritten and expanded, particularly those portions dealing with nerve degeneration and the sections on the cerebellum, thalamic nuclei, and the reticular system of the brain stem. Important additions have also been incorporated into the chapters on the prefrontal areas and the cortical projection systems. In general, there has been a page-to-page revision of the entire text, with new illustrations added. The fundamental changes make this virtually a new book, a text that can be, as in the past, highly recommended.

Aspects of the Psychology of the Tuberculous. By Gordon F. Derner, Ph.D., Associate Professor of Psychology, Adelphi College, Garden City, New York. Psychosomatic medicine monograph. Cloth. $3.50. Pp. 119. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

In this period in medical history, when the relationship of the mind-body configuration to disease is being stressed, the author considered it worth while to examine the psychological aspects of a disease with a long history of psychosomatic interest. His method of appraisal included the use of clinical interviews, standard psychological tests, and specially designed tests. The questions asked concerned the specific and characteristic feelings and reactions of the patients. The degree of psychopathology and the prevalence of *spes phthisica* were investigated. Some of the findings included (1) the conclusion that there is no unique tuberculous personality but a wide variety of disturbed behavior; (2) traumatic reaction to diagnosis of tuberculosis was reflected in projections and dreams; (3) the most frequent emotions were fear, apprehension, and depression (most patients were optimistic about prognosis but did not show *spes phthisica*); (4) the most frequent thought was desire to leave the hospital and return to active living; (5) cough was the most frequent prediagnosis symptom; (6) most frequent suggestions were for better food, more individual medical interpretation, and other services; and (7) observations were made of low affectivity, emotional impoverishment, impoverished intellectual productivity, introversion and some emphasis on body-oriented ideas on the part of the patients. Derner suggests that rehabilitative procedures coupled with psychotherapy may help the patient choose a life goal appropriate for him. The effectiveness of psychotherapy as an adjunct to the presently prescribed methods of tuberculosis treatment offers an important research problem. This report, though limited in the numbers of patients studied (32), is a valuable beginning in a fruitful field.

Experimental Atherosclerosis. By Louis N. Katz, M.D., Director, Cardiovascular Department, Medical Research Institute, Michael Reese Hospital, Chicago, and Jeremiah Stamler, M.D., Research Associate, Cardiovascular Department, Medical Research Institute, Michael Reese Hospital. Publication number 124, American Lecture Series, monograph in Bannerstone Division of American Lectures in Metabolism. Edited by Paul György, M.D., Louis Leiter, M.D., Ph.D., and S. O. Waife, M.D. Cloth. $10.50. Pp. 375, with 37 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

This timely monograph by workers who have long labored in the field will prove of interest to a large group of researchers and clinicians. The authors have assembled and correlated the most significant contributions in this major area, including much of their own extensive clinical and laboratory experience. The list of more than 700 references is a contribution in itself. The use of these references in the text gives the reader some idea of what the original authors sought to establish, but, at least in some instances, their claims appear to have been presented without critical evaluation by the present authors. Perhaps this was intentional. The order of presentation of the subject is sound—beginning with the significance of this problem that probably overshadows all else in the study of the pathological changes of the human body. The authors properly lay the ghost of the theory that old age is the cause of atherosclerosis. It is vitally important that all workers adopt their attitude, namely a dynamic approach to this difficult problem, rather than the passive observation of natural phenomena. Emphasis on the metabolism of cholesterol, lipid and lipoproteins predominates throughout. This appears justified in the light of present knowledge. The relation between metabolism of these factors and sex hormones or other sex factors receives mention, but this important key deserves more serious consideration in such a work, and by all the workers in this field. This excellent compendium will serve as a useful tool and source of information for 1953 but will require frequent revision because of the enormous outpouring of work on this subject. It is highly recommended reading.

Isotopic Tracers in Biochemistry and Physiology. By Jacob Sacks, Ph.D., M.D., Associate Professor of Chemistry, University of Arkansas, Fayetteville. Cloth. $8.50. Pp. 383, with 25 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, 1953.

Isotopic tracer techniques as applied in studying the metabolism of carbohydrates, fatty acids, phospholipids, steroids, proteins, amino acids, nucleic acids, purines, and minerals constitute some of the subject material of this text. In addition, tracer studies on the blood, photosynthesis, radioactive iodine and the thyroid, the handling of radioactive isotopes, and the measurement of radioactivity are included. The text also provides an interesting chapter on the fundamentals of nuclear physics and radioactivity that serves as a basis for understanding the more detailed and technical material that follows. Physicians and other scientists working in physiology, biophysics, and biochemistry will find this a most useful text, provided they have a good basic knowledge of the physics and chemistry concerned.

Die Wirbelsäulentuberkulose und ihre Differentialdiagnose. Von Dr. J. E. W. Brocher, Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Ergänzungsband 68, Fortschritte auf dem Gebiete der Röntgenstrahlen vereinigt mit Röntgenpraxis, herausgegeben von: R. Grashey, et al. Cloth. 78 marks. Pp. 272, with 376 illustrations. Georg Thieme, Diemershaldenstrasse 47, (14a) Stuttgart-O; [American agent—Grune & Stratton, Inc., 381 Fourth Ave., New York 16], 1953.

This work is one of a series of archives and atlases of normal and pathological anatomy in diseases that usually produce x-ray pictures from which diagnosis can be made. The author, an experienced roentgenologist, points out the frequency with which patients believed to have fibrositis, "the witches' shot" of the Germans, or the victims of rheumatic spines, are brought to the roentgenologist too late to permit an early diagnosis. He indicates that the patients on whose lesions the discussions in his book are founded, are not from hospital practice, because patients frequently enter the hospital in the late stages of their disease. He emphasizes the fact that the newer roentgenologic methods have been used. In view of the extensive bibliography appended to the text, the work is a reference book rather than an ordinary textbook, especially since the author clearly demonstrates that other conditions may closely simulate spinal tuberculosis and are difficult to differentiate without the guidance of an expert roentgenologist.

The book begins with nearly 100 pages devoted to the consideration of tuberculous spondylitis. The history of this disease is discussed briefly and, more extensively, its pathogenesis, symptomatology, laboratory diagnosis, local peculiarities, prognosis, and treatment. A final brief section in the review discusses the proper procedure in treating early cases in which, even after x-ray, the diagnosis is doubtful. The second section of the book discusses nontuberculous spondylitis of infectious origin, such as osteomyelitis of the spinal bones, the spondylitis of brucellosis, typhoid and typhus spine, and various infections of the vertebrae following abortion, sore throat, diphtheria, erysipelas, furunculosis, gonorrhea, influenza, carbuncles, leprosy, malaria, measles, cerebrospinal meningitis, pneumonia, smallpox, and anthrax. The third section covers ankylosing spondylitis, and the fourth section deals with so-called Scheuermann's disease, (also known as juvenile dorsal kyphosis, vertebral epiphysitis, vertebral osteochondritis, and juvenile osteochondritic kyphosis). The author regards this as one of the conditions most commonly mistaken for Potts' disease. Shorter sections discuss anterior fusion of vertebrae, separation of vertebrae, flat spine, congenital and acquired developmental failures, osteochondrosis, diseases accompanied by diffuse calcification, and primary neoplasms of the vertebrae.

There is an illuminating discussion of differential diagnosis, a short epilogue, nearly 10 pages of references, and a good subject index. The book is attractively bound in brown cloth;

the paper and topography are excellent, and the illustrations, a few of which are diagrammatic, are mainly excellent reproductions of roentgenograms. It is a well-written, systematic, and profusely illustrated treatise on the subject.

Individual and Community Health. By William W. Stiles, M.D., M.P.H., Associate Professor of Public Health, University of California, Berkeley. Cloth. $6. Pp. 492, with 134 illustrations. Blakiston Company (division of Doubleday & Company, Inc.), 575 Madison Avenue, New York 22, 1953.

This volume is especially well suited to the audience for which it is primarily intended, the college student. It is generously provided with excellent illustrations, and the various sections in each chapter have comprehensive lists of suggestions for supplemental reading. The discussion is presented in a well-written, easy-to-read style. The author has been careful to write with restraint but at the same time to present all aspects of the topics.

All the significant aspects of individual and community health are considered in the 17 chapters. Satisfactory orientation is provided in the opening chapter, which, by citing facts and figures, shows clearly the need for control of disease even though tremendous advances have been made within the last century. This progress is emphasized in more detail in the closing section of the book. Disease control measures are well described in a special chapter. It is difficult to select any outstanding chapters, but it can be mentioned that the consideration of sociosexual problems is especially informative, as are chapters on food sanitation, occupational diseases, maternal and child care, and the final chapter dealing with careers in medicine and allied sciences.

Pituitary Chromophobe Adenomas: Neurology, Metabolism, Therapy. A Clinical Study of the Sellar Syndrome. By John I. Nurnberger, M.D., Research Associate, Institute of Living, and Assistant Clinical Professor of Medicine (Neurology), Yale University School of Medicine, New Haven, Connecticut, and Saul R. Korey, M.D., Associate Professor of Neurology, School of Medicine, Western Reserve University, Cleveland. Cloth. $7. Pp. 282, with 35 illustrations. Springer Publishing Company, Inc., 44 E. 23rd St., New York 10, 1953.

This monograph consists of a comprehensive review of the literature on chromophobe adenomas and an analysis of 117 cases observed at the Neurological Institute of New York and the medical services of the Columbia-Presbyterian Medical Center from 1929 to 1948. The normal structure of the hypophysis and hypothalamus and the pathological changes encountered in chromophobe adenomas are described, and the neurological and metabolic disturbances associated with these pituitary tumors are discussed. Treatment by radiotherapy, surgery, and medical management are discussed briefly. The book is well illustrated and contains over 400 references.

Human Blood Coagulation and Its Disorders. By Rosemary Biggs, B.Sc., Ph.D., M.D., Graduate Assistant in Department of Pathology, Radcliffe Infirmary, Oxford; and R. G. Macfarlane, M.A., M.D., Clinical Pathologist to Radcliffe Infirmary, Oxford. Cloth. $8. Pp. 406, with 60 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, 1953.

Biggs and Macfarlane, having long experience in the field of blood coagulation, have produced a splendid monograph on this subject. The introduction deserves careful reading by all students of medicine regardless of the stage of their career. Those contemplating or involved in medical research will especially appreciate it. The complications and pitfalls of past work in this field are reviewed with care and penetrating skill. The following chapters cover the known aspects of the mechanism of clotting and much that is speculative. The second portion of the volume is devoted to disorders of blood coagulation, including fibrinogen deficiency, hypoprothrombinemia, the coagulation defect in hemophilia, platelet deficiency, natural anticoagulants, thrombosis and anticoagulant therapy, artificial coagulants, and hemostatics. As an addendum an informative section on the newly recognized Christmas disease and Christmas factor has been added.

Appendixes of considerable practical value deal with the differential diagnosis of coagulation defects, the preparation of reagents, and technical methods. A bibliography of more than 900 references represents a wise selection of world literature in this field. The extensive experimental and clinical experience of these authors adds greatly to the significance of this volume. Their observations on thromboplastin have opened new vistas in the study of hemophilia and related disorders. In a field in which knowledge and theories are still in a constant state of change, this volume stands as an excellent milepost of progress. It is recommended to physicians who are interested in the problems of thrombosis and hemorrhage.

***Recent Progress in Hormone Research: The Proceedings of the Laurentian Hormone Conference.* Volume VIII.** Edited by Gregory Pincus. Committee on arrangements: R. W. Bates, et al. Cloth. $10.80. Pp. 603, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1953.

The proceedings of the ninth Laurentian Hormone Conference, which took place in Quebec, Canada, in September, 1952, are divided into four sets of papers on (1) chemistry and biochemistry, particularly the analysis of adrenocorticosteroids; (2) diseases of adaptation, i. e., adrenocortical physiology; (3) physiology of female reproduction; and (4) the role of the growth hormone and the roles of hormones in in vitro synthesis of lipids. The papers are by experts in their fields, the presentations are clear, and the discussions are lively. Perhaps the most interesting papers to practicing physicians are those by Thorn, Jenkins, and Laidlaw on human adrenal response to stress, by Bauer and Clark on the adaptation concept applied to diseases of the connective tissues, and by Huggins, Bergenstal, and Cleveland on the adrenal in cancer. All of the papers are worth skimming, however. The book is well illustrated, indexed, and bound.

A Guide to Obstetrics in General Practice. By William C. W. Nixon, M.D., F.R.C.S., F.R.C.O.G., Professor of Obstetrics and Gynaecology, University of London, London, and Eric B. Hickson, M.R.C.S., L.R.C.P., D.R.C.O.G., Chairman, Wiltshire Local Obstetric Committee, Wiltshire, England. Cloth. $6. Pp. 301, with 35 illustrations. Staples Press, Inc., 70 E. 45th St., New York 17; 83-91 Great Titchfield St., London, W.1, 1953.

This guide to obstetrics has been written for the general practitioner, the obstetrician, and the midwife. Its authorship is unique in that it includes the professor of obstetrics at the University College Hospital, London, and a general practitioner in a semirural area. The contents of the book include: (1) obstetric questions that have appeared in the *British Medical Journal* during the past five years, (2) an analysis of midwives' calls in the county of Wilshire, (3) work in the obstetric unit, University College Hospital, and (4) the experiences of the authors. These sources have provided a very practical book that should prove useful to those concerned with obstetrics.

Normal and abnormal obstetrics are covered completely, although operative procedures suitable for the obstetrician are omitted. An excellent chapter on nursing and the practical care of the newborn was contributed by Harold Waller, a pediatrician. Analgesia and anesthesia are discussed by Shila G. Ransom, an anesthetist. The emotional aspects of pregnancy, labor, and the important period of the puerperium are intelligently discussed by a psychiatrist, Elizabeth Tylden. Simple line drawings illustrate the text, and a few well-chosen photographs have been used. Many statistical tables emphasize some of the pertinent discussion. Most chapters contain a few key references. The appendix contains a list of the contents of an obstetric bag, record forms, and useful information.

Although some of the obstetric practices do not conform with those in the United States, most principles advocated are sound. This book provides an excellent guide for those interested in obstetrics, particularly in rural areas where many women are still delivered in their homes.

QUERIES AND MINOR NOTES

HYPERTENSION

To the Editor.—*What is the prognosis of a 25-year-old white woman who has had known hypertension (140/190 to 180/110 mm. Hg) since the age of 14 and persistent albuminuria, with casts and red cells in the urine on several occasions. The patient recalls an episode of "kidney trouble" at age 8. She is asymptomatic, and there are no positive physical findings except the hypertension. Results of the following tests and procedures have all been within normal limits: complete blood count, determination of nonprotein nitrogen, a Mosenthal test, phenolsulfonphthalein excretion, intravenous pyelogram, chest roentgenogram, and electrocardiogram.*

M.D., California

Answer.—It is important to determine the rate at which the vascular disease is advancing as measured by eyeground examination, heart size, and renal function. The latter preferably should be measured by one of the clearance tests or by maximal ability to concentrate urine (Addis' test). The details of such examinations will be found in Page and Corcoran's "Arterial Hypertension: Its Diagnosis and Treatment" (Yearbook Publishers, Chicago, 1951). While the vascular disease seems to have advanced slowly, the prognosis is still not good. This outlook might be modified if it were found that pyelonephritis was the cause of the malady or that pheochromocytoma was present. It is especially important that these be investigated because of the good results that follow treatment. Although pheochromocytoma is unlikely, it is a remote possibility. Arterial pressure if persistent at high levels may be lowered by systematic and prolonged trials with hydralazine (Apresoline) hydrochloride, hexamethonium, and a low salt diet.

CALCIUM FOR UTERINE INERTIA

To the Editor.—*I recently read an article that mentioned the use of calcium gluconate for the treatment of uterine inertia and for the induction of labor. Please give more information concerning the indications and contraindications for its use.*

J. Harold Schultz, M.D., Minneapolis.

Answer:—It has been shown experimentally (*Proc. Soc. Exper. Biol. & Med.* 38:550, 1938; *Am. J. Obst. & Gynec.* 37:194, 1939) that the coordinated activity of the uterus and its reactivity to oxytocic drugs is enhanced by increasing the available calcium. This has been confirmed clinically (*Am. J. Obst. & Gynec.* 41:948, 1941), and intravenously administered calcium has consequently been found useful in the management of uterine inertia (ibid.), in the induction of labor (ibid. 54:511, 1947), and as an adjunct to oxytocics in the control of postpartum hemorrhage (ibid. 61:1087, 1951). In uterine inertia, the primary effect of calcium is to enhance coordination and to increase efficiency of contractions. This effect is observed more consistently when the obstetric conditions are favorable, i. e., an engaged head and a soft partially dilated cervix. No deleterious effects (uterine tetany, fetal distress, or the like) follow the use of calcium. The drug ordinarily employed is calcium gluconate, in a dose of 10 cc. of a 10% solution. In patients who have been selected as favorable for the induction of labor, a hot soap suds enema is given, followed immediately by the administration of calcium. Castor oil or quinine are not employed. If labor does not begin in an hour or so, the membranes are ruptured, and oxytocin (Pitocin) is given intravenously if necessary. In the case of postpartum hemorrhage due to uterine atony, in which the uterus fails to respond to oxytocics, calcium often causes an instant return of uterine tone and dramatic cessation of bleeding. Hardy has reported favorably on the routine use of an oxytocic combined with calcium and concludes that this is preferable to the use of an oxytocic alone.

There are only two instances in which intravenously administered calcium should not be used in obstetric patients: (1) when the patient has been digitalized, since it may cause the heart to stop in systole and (2) when an undelivered patient has received oxytocin, since calcium may potentiate an oxytocic effect that has been established.

IRRITATION FROM ZINC CHLORIDE POWDER

To the Editor:—*An electrician works with a mixture consisting of equal parts of zinc chloride and ammonium chloride powder, and in this work a moderate amount of smoke is produced. The work is done in a confined space, and smoke fills the room. Would occasional exposure to this material, under the above circumstances, be harmful?*

Irving Berlin, M.D., Newport News, Va.

Answer.—Zinc chloride is an active irritant to the skin, eyes, and mucous membranes and is freely soluble in water, tears, and sweat. It is a hygroscopic as well as a caustic agent. Nasal septal perforation may occur. Ammonium chloride is almost innocuous. Since this work is done only occasionally, the exposed workman may be wise to wear temporarily a respirator and may profit by the application of a "barrier" cream to exposed skin surfaces. Although the exact operation is not fully described, the suggestion is made that, if practical, a substitute be found for the zinc chloride.

RAYNAUD'S PHENOMENON

To the Editor:—*Kindly advise the optimum location in this country or Hawaii for a patient who has Raynaud's disease. She is 34 years old and shows progressive involvement of the fingers. Only 4 of the 12 months of the year are warm enough in this locality for her to be relatively symptom-free, despite the use of tolazoline (Priscoline).*

Orin Q. Flint, M.D., Delhi, N. Y.

Answer.—Raynaud's disease is rare. In most patients showing Raynaud's phenomenon a definite cause can be found, such as early scleroderma, the presence of a cervical rib, thromboangiitis, cold agglutination, cryoglobulinemia, or hypometabolism with anemia. Assuming no such cause is present, a steady environmental temperature of not less than 82 F does benefit the patient, but emotional factors, which are notably operative in vasospastic disease, are still active. The anxiety state of the patient must be allayed. Sympathectomy is useful when trophic changes or ulcerations occur.

SCLEROTHERAPY

To the Editor:—*Is sclerotherapy (not electrotherapy) for varicose veins contraindicated in cases of hypertension, cardiac disease, or arteriosclerosis and in cases in which phlebitis was present in the extremities several months previously?*

Charles H. Codelle, M.D., New York.

Answer.—Sclerotherapy for varicose veins is not contraindicated in cases of hypertension and compensated cardiac disease. It is not contraindicated in cases of general arteriosclerosis, but is contraindicated in cases of arteriosclerotic peripheral vascular disease unless the collateral circulation is very adequate. It is not contraindicated when the extremities have exhibited phlebitis several months previously, but such cases should be carefully followed for any indication of phlebitis other than strictly local chemical phlebitis. Prompt institution of anticoagulation therapy is indicated if either spreading superficial phlebitis or deep phlebitis occurs.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

BILATERAL SALPINGECTOMY

To the Editor:—*A woman, 26, had a bilateral salpingectomy five years ago for an acute recurrence of an old salpingitis. Both the patient and her husband are anxious to have children. Has a plastic tube been developed that can be sutured close to ovaries and into the uterus with even a remote possibility of successful impregnation?*

L. Nelson Bell, M.D., Asheville, N. C.

Answer.—The plastic tube to which reference is made in this query is obviously the polyethylene tube. Polyethylene has been used in various types of plastic surgery, and in the field of gynecology it has recently been used by a few surgeons in plastic tubal surgery for maintenance of tubal patency after salpingostomy for tubes occluded at the fimbriated ends, or after resection of the occluded inner portions of the tube, with tubouterine anastomosis by one technique or another. While some encouraging results have been reported, it is much too early to appraise the value of the polyethylene tube for such indications. So far as known, there has been little or no experience with it in cases in which both tubes have been previously removed, as in the correspondent's case. Cornual implantation of one or both ovaries would be the plan selected by most gynecologists to give this patient at least a theoretical chance for pregnancy. In general it may be said that gynecologists are not enthusiastic about the results with any of the above-mentioned procedures. Because of this, there are even some who consider them unjustified. The majority, however, believe them to be justified in a few cases, but only after thorough preliminary studies and only after a fair and honest explanation to the couple as to the relative slimness of the chances for success.

MÉNIÈRE'S DISEASE

To the Editor:—*A 69-year-old widow with Ménèire's disease is alone much of the time. Her attacks usually occur two or three years apart. During the past six months, however, she has had two attacks. Is there any drug she could take to help abort an attack when it first begins? This problem is important because once an attack begins she does not have time even to walk to reach help by telephone or medicament before she is completely incapacitated by the extreme vertigo.*

Gerald C. Haskell, M.D., Springfield, Ohio.

Answer.—Diphenhydrinate (Dramamine) is of some benefit in lessening the severity of the subjective vertigo in Ménière's disease, but it in no way prevents or aborts an attack. Surgical destruction of the labyrinth, according to the method of Cawthorne and Day, should be considered in cases of incapacitating vertigo, where the process is confined to one ear with a severe hearing impairment.

BISHYDROXYCOUMARIN THERAPY DURING PREGNANCY

To the Editor:—*Does bishydroxycoumarin (Dicumarol) therapy have any effect on the fetus during pregnancy? A 38-year-old woman, when six months pregnant, was treated with bishydroxycoumarin for 21 days for acute, deep thrombophlebitis. Immediately after delivery, the infant had almost exsanguinating gastrointestinal hemorrhages, which were controlled with massive doses of vitamin K. The infant had a left clubfoot but was otherwise normal.*

Joseph Alvarez, M.D., Oakland, Md.

Answer.—There is an excellent review of the subject of antepartum bishydroxycoumarin therapy by Mansell (*Am. J. Obst. & Gynec.* **64**:155 [July] 1952). Calves newly born of cows fed spoiled sweet clover hay showed hemorrhagic tendencies and were more sensitive to this agent than were the mature animals. Likewise, after therapeutic doses of bishydroxycoumarin were administered to pregnant dogs, the newborn pups showed hemorrhagic tendencies, and none survived unless vitamin K was given. In humans, varying results have been reported. In one report, a newborn baby had cerebral and severe subcutaneous hemorrhages, and in another a baby had hemorrhages of the lungs, thorax, and pericardium; however, in some studies there were no apparent harmful effects in either the mother or the child. Mansell reported on five patients who were treated antepartum with bishydroxycoumarin, and in all these cases the babies were normal. In two cases, therapy was instituted during the most critical part of the life of the fetus, that is, in the first trimester, and yet no deformities of the baby occurred. Mansell concluded, from the fact that none of his five patients aborted or had episodes of uterine bleeding and that no fetal abnormalities occurred, that, when safe levels of prothrombin time (25 to 30 seconds) are maintained during bishydroxycoumarin therapy, there is nothing to fear, so long as vigilance is practiced.

COLD TREATMENT OF SPRAINS

To the Editor:—*Modern first-aid treatment of joint injuries, such as sprains, seems to be the application of cold. Bags of cracked ice are seen on the field for immediate application to knees injured in football. Has cold therapy been demonstrated to have any advantage over the time-honored application of heat?*

M.D., California.

Answer.—The physiological basis for the application of cold in acute sprains and strains lies in the vasoconstricting effect of cold, whereas heat tends to cause vasodilatation. In an acute sprain or strain, subcutaneous hemorrhage may occur. Cold is applied in acute cases; with the intent of diminishing circulation and thereby decreasing hemorrhage and edema. Thus heat is usually not applied to a strain or a sprain until 24 to 48 hours after it is incurred. Later, when the tendency toward hemorrhage and edema formation has lessened, the application of heat is indicated in order to increase the blood flow to the area.

WATER CONTAMINATED WITH ENDAMOEBA HISTOLYTICA

To the Editor:—*Where there is risk of water contamination with cysts of Endamoeba histolytica, is boiling of the water the only reliable method of insuring that the water is free of these infectious agents? How long should the water be boiled?*

Paul E. Adolph, M.D., Wheaton, Ill.

Answer.—Boiling the water is the only reliable method of insuring that drinking water is free of the organisms in question. The water should be boiled for at least 15 minutes.

SHAVING THE EYEBROW

To the Editor:—*There has been some debate on our staff concerning the feasibility of shaving the eyebrow in cases of lacerations in that location. Some feel that eyebrows should never be shaved because they might not grow back. Others maintain that for good surgical technique the site of laceration should be shaved and also that the eyebrows always grow back. Would the physician be liable if the eyebrows did fail to grow? Can you help us settle this issue?*

Louis Gianvito, M.D., Staten Island, N. Y.

Answer.—Shaving the eyebrow in cases of lacerations requiring surgical repair is optional with the surgeon and is indicated for surgical cleanliness or to facilitate repair. Shaved eyebrows will be fully restored if not otherwise destroyed.

QUINIDINE

To the Editor:—*Has permanent impairment of hearing been reported following the administration of quinidine?*

John P. Gifford, M.D., Vero Beach, Fla.

Answer.—As far as can be determined, a search of the literature fails to reveal a report of permanent impairment of hearing following the administration of quinidine.

OPPORTUNITIES AND RESPONSIBILITIES OF THE PHYSICIAN IN WORLD AFFAIRS

CHAIRMAN'S ADDRESS

I. Ridgeway Trimble, M.D., Baltimore

One of the prerogatives of the chairman of any organization seems to be that in his farewell address it is permissible for him to stray from the narrow confines of a strictly scientific path to the broader avenue of philosophy. My subject concerns the opportunities and responsibilities given to the physician and the surgeon to aid in the prevention of the war that seems to be daily drawing closer and to make obsolete the recourse to war as the attempted settlement of political and ideological differences. This is a big order, a difficult assignment, but at the beginning I should like the purport of these remarks to be clear.

I do not want to be in the category of the politician who had been addressing a large crowd of people at some political gathering in North Carolina for a considerable time. A man attracted to the scene asked one of the listeners on the fringe of the crowd, an interested farmer, "Is he making a good speech?" The farmer replied, "He's making a powerful speech." "What's he talking about?" asked the visitor. "He ain't said," replied the farmer.

For a few moments, therefore, I would like to develop the following related thoughts: that only international understanding will prevent war; that physicians have a common language and enjoy the confidence of the people more than any other profession; that physicians know the true meaning of war better than anyone else; that politicians and statesmen and soldiers have thus far failed to prevent wars; and that physicians have a great opportunity and obligation that they must seize and fulfill without further delay.

Furthermore, I feel impelled to bring these thoughts to your attention for your critical evaluation and to stimulate your interest in this whole subject, because they represent an effort to ease the fearful burden that we are passing on to our children. From our fathers we inherited a world that was bright and full of promise. To our children we leave a world over which hovers the ever darkening cloud of a warfare so dreadful as to surpass the imagination, so dreadful that we seek to ignore it by forcing all thought of it into the background of our consciousness. We cannot sit by complacently; we must think of and plan constantly for ways and means to protect in the future those lives for which we are responsible.

THE FUTILITY OF WAR

"Important as preparedness for war may be, evidence is increasing that military success alone is no guarantee of peace. On the contrary, history would suggest that civilizations ultimately face extinction if war is their sole method for achieving international accord. Perhaps more important for our own security than perpetual mobilization is the assurance that the opposite shores of the Pacific, as well as the Atlantic, are in friendly hands. One of the most important instruments, properly used, in the cultivation of such friendly understanding is the role of medical education." [1]

To every thinking man the futility and absurdity of war is so manifest that it is difficult to realize that this is not universally appreciated. Leonardo da Vinci disposed of war in two words, "Pazzia bestialissima" (the most bestial madness).

We have the very recent lesson of the inability of war to settle world problems when we reflect that, after victory in World War I, we fought our former allies in that war, the Italians and the Japanese, in World War II; and when we reflect that, after victory in World War II, we are fighting in the Korean War against China and Russia, two of our great allies in World War II.

The farmers in North Dakota, in North Borneo, and in North Korea have the same basic desires: to have enough to eat, to have enough to wear, to have shelter over their heads, and to live in peace. The little Chinese peasant family, in that country that has always been until very recently our traditional friend, *does not want* to see its only son or any other member of his family go off to war any more than does the little American family. But none of these little families, whose sons do the fighting or who may themselves be blown to bits in this total

---

Read before the Section on Surgery, General and Abdominal at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

[1] Smyth, F. S.: Our International Responsibility in Medical Education, J. M. Educ. 26:360, 1951.

warfare, seem to have any voice in the decision to provoke or to commence a war in the present state of organization of civilization.

The late eminent biologist and philosopher, Dr. Edwin G. Conklin,[2] maintained that intolerance, bigotry, and prejudices were man-made and urged their elimination through the application of the true scientific spirit. The resemblances of all men, he believed, whether the Australian bushman or the philosophers of the most civilized countries, are greater than their differences. "Heredity is not responsible for social behavior, racial antagonisms are not born, but these antagonisms are carefully cultivated and developed."

"We may be reasonably sure, from the history of evolution, that the societies which survive will be the ones that can change to meet new conditions; and that those which crystallize their philosophies and their societies in any fixed, dogmatic form are eventually doomed. The dinosaurs were large and powerful; but the dinosaurs are dead."[3]

Mind you, I believe in arming strongly against threatened aggression and in fighting when you are attacked and your family, your home, and your country must be defended. In World War I, at the age of 17, I volunteered for the Army in 1918 and attained the proud rank of corporal in the infantry. In World II, I served as an Army medical officer four years overseas in Australia, New Guinea, the Philippines and Japan, the last one and one-half years on the staff of General MacArthur. I am still a member of the active Army reserve. As an aside, I might add that I agree with my former commander that once war is joined there is no substitute for victory.

But all this talk of war and chivalry does not preclude my thesis that by intelligent, coordinated, ceaseless effort, war as the settlement of political affairs can be made obsolete. As Nicholas Murray Butler said, "To reject eternal peace as an absurdity and as something foreign to the creed or to the temperament of any people is to proclaim oneself a barbarian and an enemy to all mankind. . . . Physical force, terrorism, despotism cannot accomplish the high ends at which civilization aims. Intelligence, sound moral standards and the spirit of service can do so, always have done so, and will continue to do so."

PEACE THROUGH INTERNATIONAL UNDERSTANDING

Shyness and unfamiliarity lead to misunderstanding, suspicion, and fear, which are largely responsible for the enmity that exists among individuals, communities, and nations today. If a driver blows his automobile horn at a motorist, he turns and scowls and looks upon the incident more or less as a personal insult. However, if he recognizes the driver as a familiar face when he turns, his irritation and suspicion vanish and he waves gaily. So often the rather fierce, forbidding look on the face of a stranger is put there by shyness and as a protective reaction. A quiet word, a casual comment, and the forbidding stranger becomes a genial companion.

Lasting peace can be possible only when people understand each other; understanding can come only when people can be given the opportunity to meet each other frequently, to listen, to talk, to discuss. The American people are great joiners and have a great affinity for traveling all over the country to meetings and conferences. Sometimes foreigners speak derogatively of this American characteristic, but it is a healthy custom. In Nashville, Tenn., I recently attended a meeting of the Society of Clinical Surgery, where members came from all over the country. In the same hotel was a national meeting of the African Violet Growers Association. They seemed to be having just as profitable a time and seemed to be spreading just as much understanding among themselves as we in our society.

Mr. Malenkov and almost all the high ranking members of the Soviet high command have never left Russia. No wonder they become introspective, ruminative, suspicious, and fearful. Think how much good it would do Mr. Malenkov to travel around a bit and attend meetings such as we do, especially such a one as the African Violet Growers Association.

Surgeons seem to travel more frequently and further to conferences than anyone else. I venture to say that had physicians and surgeons in 1861 been given the opportunity to travel and to meet and discuss their problems and to know and understand each other as we do today, they alone could have prevented the incredible catastrophy of our Civil War, rightly called by Adams the American Tragedy.

Science and learning are truly international and therefore should lead in creating international amity, so that scientific societies must take the lead in establishing cooperation and friendship among all nations. As an example of understanding resulting from free exchange of medical concepts, from frequent visiting in our medical circles, made easier of course by a common ancestry and a common language, is the close relationship between physicians and surgeons in the United States, Canada, Great Britain, Australia and New Zealand, and South Africa. I believe that our profession has played no small part in cementing the ties that exist between these countries, so close that even the wild statements released by the irresponsible pseudostatesmen of both countries cause little more than a trickle of annoyance and amusement over the calm surface of fundamental understanding that exists between us. We know and understand each other so well that we shall never fight a war on opposite sides.

UNIQUE POSITION OF THE PHYSICIAN

The trust and the confidence and the respect shown to the physician by his patients brings about a relationship that is unique. Even priests of the church cannot come so close to the man who is ill or whose family is ill as can the physician, who alone is familiar with the physical and mental requirements of his patients. He stands for hope and strength and is looked to for guidance and help.

As physicians, then, we have deservedly or undeservedly won the confidence of the common man more than have any other professional workers. The common man believes that we understand his problems and that we earnestly want to help him. We seem to him like a father in the presence of his children. Our counsel is sought for all sorts of perplexing problems in addition to those of illness. Such a relationship brings infinite power and infinite responsibilities.

[3] Winslow, C. E. A.: Economic Values of Preventive Medicine, Chronicle of World Health Organization 6: 191, 1952.

As physicians we have been educated and trained to prevent disease and epidemics, to cure and comfort the sick, to heal wounds, and to straighten the body. We, therefore, understand the dreadful ravages of war better than any other class of men. As physicians we have a common understanding in our profession throughout the world. We speak the same language.

Physicians' regard for human welfare transcends their nationalistic feeling. In 1882, cholera, always lurking in India, sneaked across Egypt to Alexandria, and all Europe was alarmed.[3a] From France, Pasteur sent his assistants Roux and Thullier; from Germany went Koch and Gaffsky. The rivalry was keen between the two commissions just as hatred was keen between Germany and France and just as bitterness was present between Pasteur and Koch. Each strove to beat the other in finding the cause of cholera.

Then one day a telegram came to the Germans, "Thullier of the French commission is dead—dead of cholera." Koch and Gaffsky immediately went over to their rivals and Koch was one of those who bore Thullier, the youngest of the investigators, to his last home. As he put wreaths over the wooden coffin, he said, "They are very simple but they are of laurel, such as are given to the brave."

Dr. Paul Hawley wrote me of another instance of this sort only last week. He stated that, when the Germans were driven out of Paris by our Army in World War II, the commanders of German military hospitals were ordered to sabotage their hospitals so that they would be unusable by the American and British forces. The German medical officers disregarded this order. In only one hospital was there any sabotage. In Hospital Beaujon, a hand grenade had been exploded in the telephone switchboard. All the rest of the hospital was ready for immediate occupancy and use, with x-ray apparatus in perfect working order, instruments in order in their cabinets, etc.

A PROUD RECORD

Our inheritance as physicians is a proud one, and our accomplishments, attained under a free system of individual enterprise, in the fight against disease stand out as the bright hopes of developmental science as opposed to the questionable advantage of other scientific accomplishments, such as the development of increasing speed, increasing explosive force, and increasing toxicity of chemical agents. As an evidence of their high regard for physicians, the general population has voted our profession the only one subject to draft in the armed forces.

The medical profession in countries throughout the world where adequate educational facilities are available has waged war successfully against such epidemic diseases and other human scourges as the plague, smallpox, cholera, rabies, malaria, typhoid, yellow fever, diphtheria, hookworm, pernicious anemia, diabetes, syphilis, tuberculosis, pneumonia, and local and general bacterial infection, to cite only a partial list of achievements. The conquests of surgery over pathological lesions and congenital abnormalities of the abdomen, chest, brain, heart, and great vessels are well known to all of you. Time does not permit the mention of victories over disease in the domestic animal and the plant domains.

There are new frontiers for medicine, particularly for American medicine, because our country has assumed the leadership of all free nations. These are the opportunities for medicine and physicians to become leaders in the field of medical statesmanship. Political statesmanship and armed might alone have not proved equal to the task. The physician, because of his prolonged and continued life of study, is trained to command. He seeks no political office and, because of that fact, his position for influence is greatly strengthened.

THE PHYSICIAN IN WORLD AFFAIRS

The influence of physicians in public affairs has waned greatly in the past hundred years. There was a time when they were civic leaders as well as professional men. To that position they must return. But they cannot return if they remain within the confines of their medical duties, pursuing blindly and furiously their limited objectives. First of all they must fulfil their primary function of healing the sick, of course, but they must raise their sights. They must use their intellect and their energy ceaselessly to plan and to act in this great struggle to prevent the destruction of civilization as we know it today.

For the physician to remain strong and to increase his influence in medical and world affairs he must remain free and independent. Commenting on the triumphs of the medical profession over disease, Dr. W. Edward Gallie of Montreal stated, "And as I think of this glorious era, I cannot help wondering if it could have happened under state medicine. Would the fires of research have glowed as brilliantly under bureaucrat direction and political control as they have in the immediate past? Could management by the civil service have been as successful in attracting these bright young minds to the study and solution of the problems of health and disease? My experience with politics and the civil service makes me doubt it and makes me think that we should avoid at all cost the introduction of socialistic changes. . . . The spectacle of what is going on in England and New Zealand with their schemes of state medicine, is quite enough to drive bright and clever young men into other fields of endeavour. At any rate there will be no sons of doctors entering medical school if state medicine comes. I would venture to predict that with the advent of socialized medicine, as it is advocated by the socialist and communist parties, this golden age of medical discovery will come to a close and we shall enter a period when progress in the study of health and disease will bog down to the speed of the civil service. The idea that medical research can be kept alive by government grants is just silly if it turns out, as I think it will, that the bright boys no longer want to be doctors and will no longer enter the schools."[4]

PRESENT TRENDS TOWARD HELP

There exists a wide and ever-increasing groping toward effective means to promote international understanding. We in America have such a strong belief that our way of life and our system of government offers the

4. Gallie, W. E.: Problems of Practice, Maryland M. J. 1:315, 1952.

best opportunity for a free, happy, and peaceful existence that we are almost childlike in our enthusiasm to convey our concepts to others. Certainly, we have no imperialistic motives. In my early memory, such organizations as foreign missions of our churches, the Rhodes scholarships, and the Rockefeller Foundation were associated with schemes to promote international good will, but only recently have I appreciated the full significance of this principle.

Whatever may be said by the critics of the outpouring of dollars, materiel, and personal effort from many individuals and agencies from the United States to the peoples of the world since World War II, it cannot be denied that all of this represents a spontaneous generosity from millions of Americans heretofore unheard of in the history of the world. Now, however, the time has come, in fact is long overdue, when we should insist that our donations be distributed in a business-like manner, fairly but economically. The supply of the old milch cow is not inexhaustible. Since the end of World War II, our government has spent 40 billion dollars through various kinds of official aid to help other countries. But along with some gratitude, we have won large measures of distrust and ill will. In many parts of the world never has our prestige been lower. This is not a dollar problem. It is a human problem. People in other countries want a helping hand, not a handout; they want dedicated help, not money bag help.

They are not won over by the mere mention of dollars, or by the gesture of throwing largesse to beggars. Our purpose should be to assist less fortunate nations to stand on their own feet. It is not the responsibility of the United States to supply enough chlorophenothane (DDT) powder to eliminate malaria in India, but to instruct the Indians, as is now being done at Delhi, how to make factories to manufacture their own chlorophenothane. "It is just this difference between doing the job for them and helping them do it themselves that will make or break our entire foreign policy. To do the job for other nations is nothing more than a continuation of the hated colonial imperialism. To help other nations become self-sufficient is the true spirit of the commonwealth of free nations, which is our objec'ive." [5]

ADVANTAGES TO OUR OWN NATION

This whole program of help to other nations holds very definite advantages to our own nation. We cannot afford to contemplate visions from an ivory tower. We are working day by day in a tough and practical world. In the first place, the commonwealth of free nations is waging a campaign against a disease that threatens to become pandemic and destroy life as we know it today. I speak not of a biological disease but of the political disease of communism. Communism thrives on ignorance, hunger, and disease.

The life-span in northwestern Europe, North America, Australia, and New Zealand (the so-called developed areas, where one-fifth of the population of the globe lives) is an average life expectancy of 63 years. In another group of "undeveloped areas," including the homes of nearly two-thirds of the world population, the life expectancy is only 30 years. This simple fact emphasizes in dramatic terms the major problems of the human race today. Morbidity takes an even greater toll of our economic resources than does premature mortality. In the case of the mosquito-borne diseases, the malaria control in the Philippines reduced school absenteeism from 50% daily to 3% and industrial absenteeism from 35% to 4%. In Liberia, there is only one physician to every 63,000 inhabitants. In India, mothers who know that 7 out of every 10 babies born to them will die in infancy or childhood are easily persuaded by the propaganda of the Communists.

One of the most important tasks we have today is to win the people of Southeast Asia into the commonwealth of free nations. Indeed, the peace of the world could well depend on it. Southeast Asia (Indochina, Thailand, Burma, and Malaya) in other hands, as it was in 1942, opens the great plains of India and Pakistan, the islands of Indonesia and the Philippines, and the continent of Australia to conquest. We recently lost the Chinese ballgame 400 million to nothing; we cannot afford to lose these other peoples as well.

It appears that by strange coincidence, our two former principal enemies, recently defeated in World War II, must in the future form our principal outposts of defense against the Communists. If these two nations can be won over to embrace the principles of democratic government, rearming them gives the free nations immeasurable strength; but if, when armed, they return to their totalitarian background, rearming them may prove disastrous. There is no surer way to win them over than to have their physicians brought into our medical orbit.

FELLOWSHIPS AND FUNDS

To promote the advancement of science throughout the world, there are an increasing number of fellowships, funds, and prizes available for graduate study and research in medicine and allied sciences, through associations, foundation funds, institutions, and others. A list of over 200 such donating agencies in Canada and the United States is kept on file by the Association of American Medical Colleges, whose headquarters is in Chicago.

There are the private funds, such as the Rockefeller Foundation and the Ford Foundation, and in recent years very valuable help has been given through two sources. One is the Fulbright Fund, which is derived from the surplus war material in foreign countries belonging to the United States and sold into commercial channels, the proceeds being made available for scholarships to and from these countries. Such scholarships are awarded on a competitive basis. The other source is through the Smith-Mundt Act. This fund provides a sum of money for leaders from other countries to come to the United States.

The World Health Organization (WHO) is a specialized agency of the United Nations. As such, it inherits the functions of the Office International d'Hygiene Publique, the Health Organization of the League of Nations, and the Health Division of UNRRA. In its seven years of existence WHO has proved that nations can work together on common problems without losing any of their national sovereignty. Its budget for 1954 is $8,487,700. The United States' share of this budget will be about one-third of the total, or $2,800,000. Assessments are made against 70 member states and three associate members.

---

[5] Moore, R. A.: New Frontiers of American Medicine, North Carolina M. J. 13:457, 1952.

Recently, the Point-4 Program has been transferred from the State Department to Mr. Harold E. Stassen, the Mutual Security Director. Point 4 was so named because it was the fourth point in Mr. Truman's 1948 inaugural address and proposed technical aid to underdeveloped countries. It was administered under an agency organized for this purpose, the TCA (Technical Administration Cooperation). Under Mr. Stassen also falls the agency that was set up to administer the Marshall Aid Plan for Western Europe. It was originally called the ECA (Economic Cooperative Administration) and was subsequently renamed the MSA (Mutual Security Agency). Under a new plan these agencies have been taken over by the new Foreign Operations Administration. There is the United Nations International Children's Emergency Fund (UNICEF), which has been doing work of the greatest importance.

The United States Public Health Service for this past year has participated in health programs of 20 countries of the Near East, Far East, and Southern Europe, as well as in 18 countries of Central and South America.

In this connection, mention should be made of the value of visiting medical teams such as those organized by the Unitarian Service Committee, working in conjunction with our State Department. These teams in Poland, Germany, Japan, South America, and other countries have demonstrated beyond all doubt that American, British, and Scandanavian medical educational methods and techniques are received with the greatest enthusiasm by these countries. The descriptions of the impression made by the first operation in Berlin for congenital heart defect by Dr. William P. Longmire, and the first pneumonectomy in Bogotá, Colombia, performed by Dr. George Humphreys, are heartening to read.

As one studies this subject, one becomes encouraged by the ever-increasing number of people donating their time and their money to such organizations as Agricultural Missions, American International Association for Economic and Social Development, Band of Christophers, CARE, English Speaking Union, Experiment in International Living, Friendship Stations, Interdependence Council, National Committee for a Free Europe, and World Neighbors, to mention only a few. Some of the individual physicians who have been keenly interested in this problem of the promotion of international understanding through medical exchanges are Dr. M. H. Clifford of Boston; Dr. Edward L. Young of Brookline, Mass.; Dr. Thomas Greenaway of Sydney, Australia; Dr. Frances Scott Smyth of San Francisco; Dr. Robert A. Moore of St. Louis; and Dr. Eldridge Campbell of Albany, N. Y.

Such facilities as have been mentioned offer great opportunities to promote science and world peace. Perhaps the most important part of this work to physicians is the training program for foreign postgraduate students. Indisputable as the advantages of such a program may be and useful as it may be to our hospitals needing house officers, nevertheless, along with many others in this country, I have been disturbed by the procedures and methods used or followed in the training of the young men in medicine from foreign countries. I use the term postgraduate student advisably, because it is through this *group that our efforts can be made most effective*. It is not my idea to recommend the addition of more foreign physicians and more foreign medical students for practice in our own country. Every medical school here has more applicants from our native population than can possibly be admitted. Also, once a foreign student is here in medical school for four years and then several years more in training, he is likely to remain in this country and not to return home, where he is really needed.

First of all, in many instances, there has been insufficient screening of these young people in their own country to give assurance that those who come will greatly benefit by the experience or be of real help to the institutions in this country. Too many people with inadequate training have come to the United States, have taken the first job that was offered to them that paid any money, and have been at times exploited by the hospital that took them on. The continuation of practices of this type will injure international relations rather than improve them.

The language barrier is a serious one. It is irritating to the nurses, physicians, and patients in the hospitals involved, and puts the foreign house officers in a bad and unfair light. Too often the reaction is, "He seems to be pretty stupid; he can't even speak English."

A second complaint of hospitals in which the foreign house officer works is that many of these men have had poor or insufficient fundamental training at home. A third objection to this whole plan is that many have come from abroad who have never had any intention or returning to their own country after finishing their training. A fourth disadvantage lies in the unwillingness of some chiefs of service in our hospitals to put out a little extra effort to train these physicians on their staffs. These difficulties are all aggravated when a resident house staff has a number of foreigners to assimilate, each from a different country.

My belief is that the most efficient way to accomplish the desired result is by a plan that would give a continuing year by year liaison for unilateral or bilateral exchange of personnel between one hospital in this country and a sister hospital in a foreign country. There should, of course, be sufficient flexibility in the plan to permit the unusual person an opportunity to visit another institution, if there are sufficient reasons to recommend such a variation.

This arrangement would carry one step further the plan of our State Department for the past two or three years, which has been to try to develop a certain geographical zone of interest by each of our medical schools. For example, Washington University in St. Louis was asked to undertake this reciprocal arrangement with the University of Bangkok in Thailand; Harvard with the University of Calcutta in India; Columbia with the National Taiwan University in Formosa; and Johns Hopkins with the University of the Philippines. There have been similar requests to other universities in this country.

So far as I know, only the arrangement between Washington University and Thailand has been agreed on and given trial. This has met with great success. Dr. R. A.

Moore, the dean of the School of Medicine at Washington University, has been a leader in this whole program. His school was the first in this country to establish a cooperative teaching program under the Marshall Aid Plan, and in 1951 received a two-year grant-in-aid from the Economic Cooperation Administration, the administrative unit for the Marshall Plan, for this purpose. The results of this have been highly successful. Groups of outstanding Siamese have come to Washington University for postgraduate work, and during this past year seven faculty members from that school of Medicine have been sent to Bangkok as part of the teaching assistance program. These seven were associate professors in biochemistry, anesthesiology, obstetrics and gynecology, pathology, physiology, and surgery.

The Johns Hopkins Medical School has not yet entered into a formal arrangement with the University of the Philippines. Such a suggestion was made by the United States Department of State two years ago, and Hopkins indicated its willingness to participate, but nothing binding has yet been arranged. Three members of our school of hygiene are leaving this month for a year's residence in the Philippines.

An independent plan of great promise has been started with reference to Japan by Dr. Eldridge Campbell,[6] professor of surgery at the Albany Medical College. This is still in the stage of unilateral exchange, but it is this unilateral approach that is the most important one, and plans should not be held up for establishment of a feasible bilateral exchange.

Eighteen months ago Dr. Campbell visited Japan and Korea as surgical consultant for the Surgeon General of the Army. Before leaving the United States he asked the surgeon of the Far Eastern Command to have a number of well recommended Japanese medical graduates available for interview, saying that he could offer them a limited number of internships and assistant residencies, and that they must pay for their own transportation. To his surprise, 42 Japanese were on hand for the interview from all over Japan. He brought four to his school, four to Chicago, and one to Cincinnati. In Albany the two Japanese assigned to anesthesiology, the one in orthopedics, and the one in neurosurgery have done such good work that there is much enthusiasm for continuing this program with Japan. They have been elevated to the resident status for the coming year. The one assigned to neurosurgery in Cincinnati has turned out to be an unusually good student, a hard worker, and very popular with the staff; he has improved a deficient surgical technique with great rapidity, and has rapidly overcome initial difficulties in language. One of the Japanese in Chicago assigned to orthopedics has done so well that he will stay on as an assistant-resident. The three others have done very good work on the pathological service.

The American Army pathologists in Japan have organized a pathological society with the Japanese. This society is concerning itself with opportunities for postgraduate study in the United States to promising young Japanese. The College of American Pathologists in this country will place the men in positions where they will gain the experience that will fit them for their job in Japan when they return home.

Approximately 40 Japanese graduates are now on the intern staff of American hospitals in Japan. Japanes medicine was based on German medicine. Their hospita histories and their scientific papers and most of thei present text books were written in German. The disintegration of German medicine has left a void in Japa that this country could readily fill.

In Germany, the University of California in Los Angeles has recently entered into a reciprocal arrangemen in a limited way between its surgical service and that o the Free University of Berlin. Professor Linder of Berli has been offered an exchange professorship in Californi Recently the College of Physicians and Surgeons o Columbia University has been working on an affiliatio with the Free University of Berlin at staff levels and a residency training levels. In this past year Dr. and Mrs Hilton Read, physicians of Atlantic City, N. J., independently arranged for 27 interns to come from Germany t some of the hospitals in New Jersey.

The chair of surgery at the Peter Bent Brigham Hospital in Boston has for a long time invited a distinguished British surgeon as temporary occupant. St. Mary's Hospital (London) is about to begin an exchange of a junio staff member with the Children's Hospital of Boston Since the end of World War II there has been an activ and mutually stimulating exchange of senior staff surgica personnel between Guy's Hospital in London and th Johns Hopkins Hospital in Baltimore.

A training program of continuing reciprocal relationship between individual hospitals in this country an individual hospitals abroad is one that might be followe by other free countries where well-established medica schools have the same thing to offer as we do, such a those in Canada, Western Europe, Australia, New Zealand, South Africa, South America, and elsewhere.

The plan for this country would include the medica school hospitals, the independent hospitals associate with medical schools, the private clinic hospitals, an independent hospitals of other categories. All of thes hospitals must meet certain teaching and training standards if first class training is to be offered the candidate selected from foreign countries.

These candidates must be carefully screened by suc responsible agents as committees from their medica schools and hospitals. They must come over here wit the understanding that they are to return to their ow countries after completion of their training. Here, th coordination might be supervised by such permanen associations as the Association of American Medica Schools or the Institute of International Education.

Language difficulties present a barrier for successfu training. The ability not only to read and write English but to understand and speak it are essential for success in this program. The foreign governments concerned, i such a program is approved, should initiate courses o study in English that would prepare the candidates fo the assumption of their duties in American hospitals. Even in the various branches of medicine in this country, medicine has become so specialized that it seems that each group "can communicate only with those immured in the same mausoleum." A happy and unusual feature of the plan is that much of it could be carried out without subsidy from the government, but should have the approval of the State Department.

---

[6] Campbell, E. H.: Personal communication to the author.

In all this effort, Americans should approach the problem vigorously but with humility, remembering the words of our own Secretary of State, John Foster Dulles: "Among other peoples, the Japanese, the Indians, the Mexicans, to name only a few, there are many who possess a love and appreciation of beauty, a capacity for human understanding and a richness of sympathy which we might well covet for ourselves. If we apply a true measuring rod, we will approach them humbly and not in a mood of lofty superiority."

CONCLUSION

In conclusion, I wish to restate that the physicians, who enjoy the real confidence of their people more than any other profession, who know the true meaning of war better than anyone else, and who have been given superior education, have a great opportunity and a great responsibility for world peace. They must assume leadership, they must not rest, they cannot die until they have by ceaseless application of their trained minds worked out and put into practice plans that will bring to their own children and to the world the one opportunity they may have to escape the disaster that daily appears more threatening. We must remember: "There are times when the future of this world of ours seems rather grim; and voices of discouragement and dispair are heard in many quarters of the globe. Since the days of the caveman, however, this earth has never been a Garden of Eden, but rather a Valley of Decision, which calls for all the toughness and the resilience which the human race has at its disposal."

CHRONIC BLADDER IRRITATION IN FEMALES

H. A. O'Brien, M.D.
and
Joseph D. Mitchell Jr., M.D., Dallas, Texas

"Bladder trouble" is extremely common in females of any age. In most of our patients with this complaint, we found the cause to be a simple infection in the urethra and trigone. To accurately determine the frequency of this lesion in our practice, we analyzed the records of 200 consecutive female patients seen for the first time in the office. It showed that in 74.5% the symptoms resulted from primary disease in the urethra and trigone. The remaining 24.5% had a variety of urinary tract disorders as seen in a general urologic practice. These were diagnosed as urethritis and trigonitis, 149 patients (74.5%); kidney and ureter stones, 23 (11.5%); acute and chronic pyelonephritis, 9 (4.5%); solitary renal cyst, 3 (1.5%); cystocele, urethrocele, or procidentia, 2 (1%); ureteral stricture and tumor, 2 (1%); exstrophy of bladder, 1 (0.5%); carcinoma of bladder, 4 (2%); ureterocele with hydronephrosis, 1 (0.5%); nephroptosis, 1 (0.5%); stress incontinence, 2 (1%); hydronephrosis, 2 (1%); and parathyroid adenoma with stone, 1 (0.5%). Since 75% of our new patients had lesions in the urethra and trigone, a further analysis of 200 of these cases was carried out to determine what common characteristics, if any, existed. The results of the study form the basis for this report.

The ages of these 200 patients ranged from 20 months to 78 years, with the greatest number in the middle years; 153 (76%) were between the ages of 30 and 60; 5 under 9; 3 between 10 and 19; 19 between 20 and 29; 13 between 60 and 69; and 7 over 70. This would indicate the importance of trauma as an exciting factor.

CAUSE

Infection in the urethra and trigone is the basic lesion in this group. Cause for this infection is not obvious. Glandular structures have been demonstrated at the external orifice and surrounding the distal portion of the urethra as well as in the submucosa of the proximal portion of the channel. Because of the position of the urethra and because of its wide caliber, it is reasonable to assume that these glands could be infected by direct contamination and ascending infection and that thus a focus could be set up in the glands that could persist for months or years. In addition, there is lymphatic communication between the cervix and base of the bladder, offering a further route for entrance of infection to this area.

The focus having been established, exacerbations can occur periodically to produce attacks of pyelitis in infants. In our young patients, these were actually attacks of acute urethritis and cystitis. The irritation from this focus can explain cases of enuresis in little girls. It may be a reasonable explanation for "honeymoon cystitis" in which trauma serves as the causative factor. This same mechanism explains postpartum and postoperative cystitis resulting from trauma to a latent urethral focus by the catheter passed to relieve bladder retention.

SYMPTOMS

The analysis showed that symptoms reported by these patients fell into three main groups, namely, urinary, referred pain, and nervousness. The common urinary symptoms were frequency, urgency, dysuria, nocturia, and lack of a sense of relief after voiding. Symptoms were not constant in all patients. In some, they occurred in attacks lasting one to several days. Attacks occurred at intervals of weeks to months, gradually increasing in severity and duration (table 1), with finally only short intervals of freedom from symptoms. Prominent in these histories is the chronic recurrence of symptoms. One 51-year-old patient stated she had had "bladder trouble"

Read before the Section on Urology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

all her life. Also we found that acute cystitis could be readily controlled with medication but that it kept recurring at varying intervals until the cause was eliminated. It was also evident that recurring attacks of bladder irritation, regardless how mild, indicated disease of some type in the urethra or bladder.

Pain was the second commonest complaint occurring in 46.5%. The areas involved were suprapubic, 28 patients; right and left groin and pelvis, 13; lower extremities, 5; lower abdominal quadrants, 9; renal areas and flanks, 28; and lumbosacral, 10. It was an aching or burning pain constant in location, often varying with the intensity of bladder symptoms, and never associated with underlying tenderness. It was easily distinguished from the sharp, localized pain of acute cystitis. The referred pain in the abdomen, back, and legs with mild urinary symptoms, so common in chronic cases, can cause confusion since it may simulate pain of intra-abdominal, pelvic, or renal disease. A patient with slight bladder irritation and right flank pain had a right nephropexy, later, a right pyeloureteroplasty, and, finally, a right nephrectomy because of staghorn stone formation. The pain persisted and was relieved after elimination of an infection and stricture in the urethra. In this series, 18% of the patients had abdominal or pelvic operations to relieve pain that persisted postoperatively and that was relieved by correction of pathological changes in the urethra. It may be easy to assess the urethra as the cause of pain that is from other origin; only after all organic causes are eliminated can pain be attributed to the urethra.

TABLE 1.—*Duration of Symptoms*

Period of Attacks *	No. of Cases	Now Having Acute Attacks
Less than 1 year	15	3
1 to 5 years	34	13
6 to 10 years	13	3
11 to 15 years	10	4
16 to 22 years	13	5
Several or many years	32	4
Totals	117	32

* Before patient was first seen.

In this group, 28% complained of nervousness from the bladder irritation. Some suffered more from the nervousness than from the bladder irritation. Patients usually found this symptom hard to describe other than by saying flatly that they were nervous and it was caused by the bladder. Others mentioned bladder symptoms only until treatment caused improvement; then they described a sense of relief from nervousness. We found that nervousness was not related to duration but rather to severity of bladder symptoms. Treatment usually brought early relief from this nervousness. A common example of this type of complaint was seen in a capable, healthy, middle-aged woman executive. She had to take sedatives at work because of increasing nervousness. Urinary frequency, without dysuria, had bothered her for several years. Finally nocturia so disturbed her that sedatives were needed for sleep. Urinary tract study revealed a chronic granular urethritis and a tight urethral stricture. With treatment there was early and marked improvement in the nervous symptoms; the urinary symptoms were relieved after elimination of urethral abnormalities.

PATHOLOGY

The pathological findings in the order of their frequency included urethral stricture in 161 patients; granular urethral mucosa, 150; papillary masses in the urethral mucosa, 68; acute cystitis, 32; trigonitis, 33; cervicitis and vaginitis, 30; bladder trabeculation, 8; chronic Skene's abscess, 1; urethral cyst, 2; senile vaginitis, 6; female prostate, 5; trichomonas, 7. Urethral stricture was the commonest lesion, being present in 80.5%. It was found at either urethral orifice, with a slightly higher occurrence at the internal orifice. These strictures varied in size and resistance as in the male. In calibrating the urethra, bulbous bougies were used and no. 26 French catheter accepted as the normal caliber. Strictures in this group ranged from no. 14 to 24 French; the average size was equal to a no. 20 French catheter. We found symptoms just as severe from the wide as from the tight strictures. In three patients, trabeculation of the bladder was also found. Patients with stricture equal to a no. 14 to 16 French catheter complain of slowness and dribbling of the stream but not of straining to void as in the group with fibrosis at the internal orifice requiring resection.

The second commonest pathological finding was evidence of chronic urethral infection observed in 75% of the cases. This was primarily a granular process in the mucosa of the proximal urethra. Thickening or edema, with increased congestion of the mucosa, were also present. In children, the granulations, when present, were very fine, but the changes usually seen in the mucosa were edema and congestion. There was no definite correlation between the duration or severity of symptoms and the degree of pathological change in the urethral mucosa. In 93% there was an associated urethral stricture.

Papillary masses of varying size, shape, and number were found in 34% of the patients and always in association was stricture or evidence of infection in the urethral mucosa. Their presence did not signify unusually severe infection, and their removal alone did not relieve any of the patients. They have been observed in patients without symptoms, but in these the urethra was otherwise normal and there was no stricture.

In many there existed an associated mild trigonitis, not always mentioned in the findings in our records. Actually, this is an extension of the inflammatory process from the urethra. In 33 cases, however, the trigonal changes were pronounced because of the formation of a pseudomembrane over all or part of this area. In these patients, urinary symptoms were usually severe and constant, and these patients required more than the average period of treatment. In over 50%, we found associated infection in the cervix that could be responsible, in part, for this trigonal lesion.

In the patients with acute cystitis, there was usually an explosive onset with severe bladder pain and often gross hematuria. Most of these patients were not cystoscoped in the acute stage, but the few examined showed intense congestion of the vesical mucosa, with areal hemorrhages in the mucosa. In all of the cases in this series, there were the associated changes of chronic nature in the urethral musoca and urethral stricture.

In females, study of the urinary tract is not complete without pelvic examination. In this group, 30 patients had some degree of cervicitis or vaginitis, although the primary symptoms were urinary. It is difficult to cure infection in the urethra and bladder with infection persisting in the vaginal tract. This is particularly true of vaginal infections caused by Trichomonas.

In five patients in the group, we found fibrous obstruction at the internal urethral orifice severe enough to require excision. In these patients, there was associated trabeculation of the bladder. The tissue removed was fibromuscular and showed chronic infection. No glands were present in these patients, although we have found them in others not included in this survey.

URINE FINDINGS

The urine analyses were particularly interesting, since they showed that, in a group of 200 patients complaining of bladder irritation, 65% had normal urine (table 2). Due to the normal urine, many patients had been considered nervous or as having irritable bladders, and examination of the urinary tract had been deferred. Of the remaining 70 patients, 40 had pus (1 to 4 +) in the urine, and in 32 of these there was no pus in the kidney urine. On this basis then the pyuria encountered in 80% of these patients was limited to the lower urinary tract.

PYELOGRAMS

In urologic study, the urethra and bladder are first observed. Positive findings here may make further study seem unnecessary, if the history indicates only urethral or bladder irritation. It is necessary, however, to complete the study or major pathological changes may be overlooked in the upper tract. Several years ago, a patient with the history and findings of urethritis was found to have a tumor of the right kidney. For this reason, we try to make a complete urologic study, including pyelograms. In the 200 patients studied the diagnoses, based on pyelograms, include normal, 170 patients (85%); slight ureteral dilatation only, 6 (3%); slight pyelectasis, 6 (3%); normal ectopic kidney, 1 (0.5%); and congenital anomaly, but no disease, 4 (2%). No pyelograms were made of 13 patients (6.5%). In 6%, we have reports of normal pyelograms from the referring physicians.

TREATMENT

Treatment is basically simple but may be prolonged in some cases. The problem is to correct the stricture when found and to destroy infected tissue in the urethra and trigone. Thirty-three patients in this group had symptoms of acute cystitis that were controlled with antiseptics and antibiotics. In the remainder, medication, either oral or local, was of little value. Local treatment was needed to eliminate the urethral and trigonal disease.

Dilation of the urethral stricture to no. 30 French catheter was the only treatment given to 52 patients (26%). This was carried out at weekly intervals using Van Buren sounds for men. The dilatations are usually carried to no. 30 French catheter and rarely to no. 32 French catheter but never beyond. Reactions can occur after dilatation with acute cystitis and pyuria as seen in the male. Strictures vary considerably, in response to treatment; some dilate slowly and others very readily, the average requiring 10 dilatations. We prefer not to dilate any stricture forcibly, and we use local anesthesia to minimize trauma for the most sensitive patients. Once dilated, the stricture is checked every three months for a year to discover recontraction. It is dilated again if necessary.

In 13%, fulguration was the only treatment given; these patients had been dilated, when needed, by the referring physician. Using a Bugbee electrode through the Pan endoscope, the lightest possible fulgurating current was used to destroy granular and papillary areas in the urethral mucosa. About half the diseased tissue was destroyed at one time, the remainder six to eight weeks later. After using a very light current, we have not observed any harmful effects from fulguration. Any scarring that might have resulted was obscured by healthy mucosa seen after healing from fulguration. We had no increased difficulty with strictures after fulguration. Fulguration was never carried out in a urethra that was strictured or spastic. When needed, dilatations were always given first. In 60% of this group, treatment consisted of a combination of dilatations and fulguration as outlined above.

TABLE 2.—*Results of Urine Examination of 200 Patients with Urethritis or Trigonitis*

Urine	Cases No.	Cases %	
Normal	130	65	
Few pus cells	20	10	80% had no pus in kidney urines
Pus +	12	6	12% had a few pus cells in one or both kidney urines
Pus ++	8	4	
Pus +++	7	3.5	8% of specimens not examined
Pus ++++	14	7	
Gross hematuria	9	4.5	

In a small group, 16.5%, severe bladder symptoms resulted from pseudomembranous formation on the trigone, with advanced underlying trigonitis. Either urethral or cervical disease was present in all of these patients. Oral medication and instillations had no effect on this infection. Only by piecemeal fulguration of this entire pseudomembranous area were we able to relieve these patients, and then relief from symptoms was striking.

Five patients (2.5%) in the group had bladder neck obstruction requiring transurethral resection. Each patient had had symptoms for many years, with increasing difficulty in voiding. One patient had 1 oz. of residual and another 3 oz., while the others emptied the bladder completely. Four grams of tissue were removed in one patient; in the others the weight ranged from 2 to 3 gm. The operations were difficult, and the results were only fair. Three of the patients needed a periodic urethral dilatation in from one to three months. The five patients requiring resections in this series are typical for our experience over the past 15 years. Other forms of treatment included excision of a urethral cyst in two patients (1%) and destruction of Skene's gland in one (0.5%).

RESULTS OF TREATMENT

This group was treated in 1948 and 1949 allowing at least a three year follow-up for evaluation of results. Of the original 200 patients, 184 were contacted and gave the following report. 1. Bladder symptoms were relieved and have not required further treatment in 75%. 2. Treatment was stopped before discharge in 12%, and these patients had one or two recurrences. Further urethral dilatations relieved them, and they are satisfied to continue without further treatment. 3. Nocturia occurred one to three times in 6%, but these persons consider themselves free of "bladder trouble." 4. Partial relief was obtained in 4%, but treatment was discontinued because it was too painful or was followed by increase in bladder distress for 24 to 48 hours. These patients tolerate poorly any type of instrumentation. 5. Two per cent are still under treatment and require dilatation every one to three months. 6. Attacks of acute cystitis recurred in 1% in spite of our efforts to remove every known cause. The results were better than we expected. Of the entire group, 75% are completely relieved, and an additional 18% are comfortable and do not feel the need for further help. In 5%, the treatment failed to relieve the patient or could not be tolerated.

SUMMARY AND CONCLUSIONS

Symptoms of bladder irritation are very common in females, particularly in the middle years. The common complaints in these patients are urinary symptoms, referred pain in abdomen, back, and pelvic area, and nervousness. The common causes for these symptoms are urethral stricture, chronic urethritis, and chronic trigonitis. In 65% of the group studied, the urine examination was normal. Treatment should be simple and should be aimed at dilatation of the stricture and destruction of infected tissue in urethra and trigone.

1414 Medical Arts Bldg. (Dr. O'Brien).

MANAGEMENT OF VESICOURETHRAL DYSFUNCTION IN WOMEN

Russell B. Carson, M.D., Fort Lauderdale, Fla.

Dysfunction of urination in the female is so common that many women have remarked: "I thought it was normal for all women to have bladder trouble." Dysfunction of urination in the female differs from that in the male, in large measure because of the difference in fixation and support of the urethra. In the male the urethra remains in a stationary position attached more securely to the pubis anteriorly; a more complete urogenital diaphragm supports it inferiorly; and the vaginal cavity is absent postero-inferiorly.

The frequency of the occurrence of some form of female urinary disturbance in the office records of my private urologic practice has stimulated this report. Of the last 2,348 patients seen in the office, 1,000 were women, and 1,348 were men. Of these 1,000 women, 529 had some symptoms referable to dysfunction of the urethra or bladder as a primary complaint. Four hundred seventy presented other complaints not referable to the urethra or bladder as their primary reason for consultation.

Diagnoses in 529 Female Patients

Disease	No. of Patients
Urethritis	199
Acute	19
Granular	101
Chronic, with stricture	63
Chronic, with polypi	16
Urethral caruncle	43
Cystitis	289
Acute, simple	160
Follicular	8
Hemorrhagic	44
Chronic	59
Interstitial	18
Bladder neck contracture	18
Bladder tumor	17
Lower ureteral or bladder calculus	12
Pyuria, cause undetermined	9
Bacilluria, cause undetermined	6
Diverticulum of urethra	6
Stress incontinence	14
Vesicovaginal fistula	2

In addition to the conditions shown in the table, 59 women had cystocele, 46 had rectocele, 15 had urethrocele, 3 had multiple sclerosis, 21 had diabetes (previously undiscovered in 9), 1 had pernicious anemia, and 17 had endocervicitis. The following data were recorded concerning the marital status and sexual experiences of these patients.

Married	690	No sexual experience	186
Single	186	Sexual experience	814
Widowed	88		
Divorced	27	Never pregnant	39.8%
Separated	9	One or more pregnancies	60.2%

The management of vesicourethral dysfunction begins with an adequate history of the complaints. The history must include (in addition to the usual complaints of frequency, urgency, nocturia, dysuria, genital or low back area aching or pain, etc.) the occurrence of previous urinary disturbance, particularly during childhood, the history of abdominal and pelvic surgery, stress incontinence, and emotional or sexual maladjustments.

Examination of the patient with dysfunction commences by having the subject disrobed and placed in lithotomy position. No successful examination can be carried out with the patient in any other position. One should begin with the general physical examination, include a brief neurological examination, and conclude with the urologic survey.

The urologic examination includes the abdomen, kidneys, ureters, suprapubic area, and back and inspection and percussion of the renal areas. The external genitalia are inspected; the labia are spread wide, and the area is well lighted to observe vaginal discharge, Bartholin cysts, Skene's gland infection, caruncle, carcinoma, erosion or prolapse of the urethral meatus, estrogen deficient vaginitis, etc. The physician proceeds then to digital examination of the urethra, testing for induration, ten-

---

Read before the Section on Urology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

derness, discharge, urethrocele, sacculation, estimation of the length of the urethra, and test of mobility of the urethra (sliding urethra). Bimanual examination of the trigone, bladder floor, lower portion of ureters, and pelvic organs follows. The genitalia are cleansed, and a small catheter is passed to obtain a sterile specimen for analysis, stain, and culture. The examination may conclude here, and in the majority of instances a diagnosis can be satisfactorily established and appropriate treatment recommended. The urologist may continue. Bladder inspection will be facilitated if the bladder is not drained of urine, providing the urine is not too cloudy for adequate inspection with a lens instrument. Intravesical inspection is followed by no discomfort if little or no irrigating fluid is added to the bladder. At the patient's second visit, residual urine should be measured. The urethra should be calibrated, and an instrument of suitable size with forward vision or an instrument with Foroblique vision, should be used to visualize the urethra and bladder. A right angle lens is of no value in the urethra but should be used in the bladder inspection. Anesthesia should not be used. Completion of the urologic study may be carried out with roentgenograms of the upper urinary tract, by retrograde or intravenous routes, and by other methods of special investigation not pertinent to the present consideration. With an accurate knowledge of the dysfunction, the urologist can proceed to correction. From statistical observation of the 529 female patients presently reviewed, the commonest urethral problem is chronic granular urethritis, of which there were 101 cases.

CHRONIC URETHRITIS

Chronic urethritis of the female simulates the chronic urethritis observed in the posterior urethra of the male, secondary to urethral stricture. Polyps may or may not be present and are of significance only in confirming the chronicity of the urethritis. From my observation, the condition is the result of urinary stasis that may have its origin from the urethral meatus to the vesical neck. It is my feeling that infection is not the intrinsic cause of this type of urethritis. The urine is frequently found to be clear on microscopic examination and negative in culture. Chronic urethritis is found in all age groups in which obstruction of the lower urinary tract is present. Hodges[1] has recently called attention to the prevalence of chronic urethritis in girls. Although he states that evidence of urethral obstruction was lacking in all but 1 of 25 girls, he does admit: "We are reluctantly forced to conclude that the reason for improvement in chronic urethritis in patients subjected to urethral dilations is not clear." It is a general conclusion by physicians who are familiar with chronic granular urethritis that the treatment of choice is repeated urethral dilatations. Except in the presence of infection, either local or systemic chemotherapy is not necessary. It is also common experience that the dilatation will last only a specific length of time for each person, and, when contraction has again taken place, relief of the recurring symptoms can be obtained by repeating the dilatation.

In the presence of a meatus stricture, caruncle, or other obstruction, the coexisting granular urethritis will not respond until adequate relief of this obstruction has been obtained. Likewise, the obstruction is not always intrinsic but may be the result of extrinsic obstruction, such as occurs in association with urethrocele or the sliding urethra, in which the angulation of concavity of the urethra is increased and the downward thrust action of the base of the bladder is lost. It is frequently observed that the patient with granular urethritis has little nocturia compared with the frequency present during the early morning hours after arising. Perhaps the exaggeration of symptoms results from urethral angulation when standing. Retention, it is felt, need be only that which is retained in the urethral canal, not a measurable quantity or sufficient to produce vesical alteration.

Urethritis should be treated by gradual urethral dilatation at one to two week intervals, which should be repeated until a normal caliber of 28 to 32 F. is maintained. The dilatation procedure is repeated every three to six months as a preventive measure. Meatotomy is necessary for all strictures failing to respond to dilatation. Faulty supports of the vesicourethral area are corrected either by pessary or by corrective surgery. The urethral and vesical plastic procedure must (1) immobilize the urethra, (2) lengthen the urethra, and (3) elevate and support the vesical floor if success is to be obtained.

URETHRAL CARUNCLE

Urethral caruncle, and obstructing, usually painful lesion, has been the basis of much speculation as to etiology and much divergence of opinion as to treatment. Palmer, Emmett, and McDonald[2] have presented a review of literature on this lesion and a study of 120 cases. Their conclusion is that the urethral caruncle represents a regional or a circumscribed urethral mucosal prolapse or both. The lesion may be easily overlooked. It may vary in size from a pinhead to a walnut, averaging the size of a small pea. It is usually single. The size and location of the lesion determine the treatment, but in any event it is directed toward palliative and symptomatic relief, since the tendency to recur is so high. (Two-thirds of the lesions recurred in the series of Palmer and co-workers.) The treatment may include locally administered caustics or local needle fulguration, radium or roentgen therapy, or radical excision by either sharp dissection or high-frequency-current cutting and coagulation.

CYSTITIS

In 289 of this series of 529 women, the working diagnosis was some form of cystitis. The simple, hemorrhagic, and follicular types usually have a sudden onset, with frequency, burning, bearing down pressure, stranguria, and pain in the genital region, lower abdomen, or sacral region. The etiology and diagnosis need not be reviewed at this time.

Management of acute cystitis is directed toward immediate relief of the painful symptoms. Nothing is superior to local application of heat, a bladder sedative such as Kerwin mixture, and chemotherapy with either a sulfonamide or an antibiotic.

CHRONIC CYSTITIS

The persistent or recurrently irritated vesical presents an entirely different problem from that of the acutely inflamed bladder. Chronic urethritis can be considered a symptom, giving evidence of some underlying anatomic or physiological dysfunction, except in those instances of specific infection such as tuberculosis, or syphilis. In the vast majority of patients, it was an associated finding that accompanied cystocele, urethrocele, vesical neck contracture, or urethritis. In some of the reported cases of pyuria and bacilluria of undetermined cause, chronic cystitis, with which no discoverable neurogenic or other urologic lesions occurred, was demonstrated cystoscopically. Three patients with multiple sclerosis presented evidence of chronic cystitis. Two of these patients complained of spontaneous uncontrollable bladder evacuations at unpredictable times. The other patient with multiple sclerosis was bedridden for three years, and vesical calculi finally developed after many months of chronic cystitis.

Chronic endocervicitis was the only discoverable cause for persistent bladder symptoms in 17 patients, and therefore it is listed as an associated finding that has definite relationship to vesical dysfunction. The treatment in these cases was, of course, directed toward the cervix rather than toward the bladder.

According to the statistics from this study an unusually large number of patients with interstitial cystitis have been encountered. In each, the cystitis has been confirmed by cystoscopic observation and bladder capacity measure. Tracy Powell's [3] deductions regarding the relation of the lymphatic system of the bladder to that of the lower abdominal and pelvic organs in the female seem the most logical explanation for the development of Hunner ulcers. In spite of my failure to gather accurate data on the association of previous pelvic disease and surgical procedures, I am firmly convinced that more than a majority of the patients in this study have had extensive pelvic surgery before the development of vesical symptoms.

The treatment of chronic cystitis is directed toward correction of the underlying cause. Urinary sedatives, hot douches, and weeks and months of therapy with sulfonamides or expensive antibiotics are deplored. The lithotomy position for thorough examination is most imperative. Gynecologic and urologic consultation are most valuable, for no patient is more grateful or more loyal than the woman relieved of the nagging discomforts of an irritable, irritating bladder. The management of Hunner ulcer is unsatisfactory at present; however, there is hope that from future studies improved methods of providing lymphatic circulation in the bladder wall will provide a method of alleviating this distressing condition.

BLADDER NECK CONTRACTURE

With the McCarthy panendoscope, the Lowsley-Peterson endoscope, or a similar instrument, a circular ring of contraction is evident at the internal urethral orifice. This contracture ring in the female resembles that seen in the male except that it is more symmetrical and there is less likelihood of a disproportioned hypertrophy of the posterior commissure. The contracture ring is fibroelastic and dilates easily only to quickly resume its contracted state again. The trigone seems to fall away at the vesical neck, and to visualize it one must elevate the eye piece of the telescope to an almost vertical position, even in the absence of a cystocele. The bladder reveals trabeculation and frequently cellule formation. A chronic cystitis, often manifested by bacilluria, is observed. This condition has been encountered 18 times in the present series.

Palliative relief for vesical neck contracture can be obtained by wide dilatation of the urethra with the assistance of local anesthesia. The dilatation must be maintained by frequently repeated treatments. More satisfactory results can be obtained by transurethral resection of the vesical neck, in which the entire circumference of the vesical neck is removed. Follow-up dilatation of the vesical neck is imperative to prevent secondary fibrous contracture. No remarks will be included here regarding the management of bladder tumors and vesical calculi, which also produce vesical dysfunction.

DIVERTICULUM

I again [4] wish to urge that examination of the urethra include stripping of the urethra and visual search for the frequently overlooked diverticulum. This sacculation deserves more attention than it has previously received. Visualization of the orifice may be difficult, but, if the outline of examination previously described is adhered to, the diverticulum can be felt and the contents visualized as it is stripped from the urethra.

The preferred treatment of urethral diverticulum is surgical eradication of the sac. Small sacculations may be destroyed transurethrally, but, if their capacity is greater than 2 cc., they should be removed transvaginally. Incision and drainage have been used on one patient in the group of six. Excision through the vagina was accomplished in three; one was not treated, and the other has been maintained with minimal symptoms by having the patient strip her urethra after each voiding.

ANATOMY AND PHYSIOLOGY

So that one may understand the various dysfunctions of micturition in the female, a clear understanding of its mechanism must be borne in mind. These mechanisms may be studied by both cystourethroscopic and roentgenologic means. Nordenstrom,[5] Hinman,[6] and Briney and Hodes [7] have studied the shape, course, and activity of the female urethra and bladder, both in normal subjects and in subjects with stress incontinence. The urethra of an adult woman is a curved tube about 4 cm. long, embedded in the anterior vaginal wall with its direction downward and forward and its slight concavity directed forward, following to some degree the contour of the inferior and posterior surfaces of the pubis symphysis. When the urethra is dilated, its diameter is about 6 mm., but the canal is capable of distending to 10 or 11 mm. The distal two-thirds of the urethra is outlined by stratified squamous-type mucosa that is continuous with the lining of the introitus. The internal one-third is lined with transitional cells continuous with the trigone. The canal in the relaxed state is pleated with longitudinal ridges that tend to gather at the external orifice and spread out onto the trigone at the inner orifice. The mucosa is a pale reddish color and is liberally supplied with shallow coursing vessels similar to those observed on the trigone. In the loose submucosa is a vascular bed simulating erectile tissue. The lymphatics are large, spacious, and drain into the inguinal and pelvic nodes. An especially rich nerve supply is derived from the hypogastric plexus of the sympathetics and from the sacropudendal plexus.

[7] Briney, A. K., and Hodes, P. J.: Urinary Incontinence in Women: Roentgen Manifestations, Radiology 58: 109-112 (Jan.) 1952.

On urethroscopic examination the meatus is entered through a slit or inverted V-like opening. The appearance of the meatus resembles the introitus mucosa except for the observed openings of large and small periurethral glands and the longitudinal folds. On distending the meatus with irrigating fluid one sees the folds flatten out, and immediately observes a shallow cavity resembling the fossa navicularis of the male. Proximal to this is a slightly concave straight-walled canal of about 1 to 1½ cm. in length. The canal then enlarges in its midportion until the mucosa again is puckered by the contracted voluntary compressor or sphincter urogenitalis. Proximal still, the urethroscopic appearance resembles the prostatic urethra from verumontanum to vesical neck in a funnel shape. The lining mucosa changes to a more glistening smooth-surfaced vascular membrane that gradually spreads out onto the trigone, in the relaxed state, or maintains a rounded canal form as far as the fairly sharply demarcated vesical neck, if voiding is actively inhibited.

The trigone and the urethra are continuous in appearance cystoscopically. The trigone angles posteriorly about 30 degrees and is outlined by the ureteric ridges on either side and the dip of the bas-fond posteriorly. Its surface is smooth, glistening, and an abundance of superficially coursing vessels are observed. In contrast, the bladder, when it is not distended, is thrown into rugae-like folds, is of paler (yellowish) color, and is of less vascular appearance. On filling, the bladder walls are also smooth. The angle of junction of the lateral and anterior walls of the bladder with the urethra is approximately 60 to 75 degrees when it is filled to normal capacity. These anatomic observations bear definite significance when one is studying a bladder for its dysfunction. Observation of the urethra during the act of urination demonstrates the descent of the base of the bladder and a funnel formation of the internal one-third of the urethra. At the same time there is relaxation of the compressor sphincter urethrae and a straightening of the canal.

The downward thrust of the base of the bladder is followed by contraction of the lateral walls and the dome so that the contraction of the dome directs the force downward toward the vesical outlet. If there is insufficient fixation of the urethra and/or the floor of the bladder, a "sliding urethra" results and the urethra and bladder appear to crawl out from beneath the pubis symphysis. The result is an increase in the concavity of the urethra and an increase in the urethrotrigonal angle. The expulsive force is directed through the trigone toward the anterior vaginal wall. Retention of urine results. The female lacks the strong ejaculatory action of the male that assists in the complete evacuation of the urethra and bladder. If there is vesical outlet obstruction and weakness of contraction of the detrusor at the dome, the contraction will result in an upward expulsion force and the effect of voiding into the dome occurs. Here, too, urinary retention is the result, and it is in these persons that a second, but smaller, voiding often takes place. In neither instance is there a herniation of the bladder or urethra (cystocele or urethrocele), but the extrinsic obstruction is just as effective in producing dysfunction as an intrinsic obstruction would be.

SUMMARY

A review of the reasons for consultation of the last 1,000 female patients seen in private urologic practice is presented. Of these patients, 52.9% were found to have lower genitourinary tract dysfunction as the primary pathological process. An explanation is offered for the frequent occurrence of chronic urethritis, called sliding urethra in this study. The management of some types of urethral and bladder dysfunction is outlined.

403 Sweet Bldg.

Use of Iron Medication.—It has been emphasized repeatedly in recent years that (1) iron can be expected to give satisfactory results only when administered to patients with an iron deficiency, which is almost always due to chronic hemorrhage, and (2) the dosage of the metal must be adequate. For a number of years I have attained entirely satisfactory results by giving enteric-coated ferrous sulfate tablets, 0.3 gm. (5 gr.), three times a day before meals. If the desired effect does not occur within two weeks, the dosage is doubled. I have not observed that the addition of anything else, including copper, vitamins, etc., has ever enhanced the effect of iron alone when given in the proper dosage.

We now have a preparation of iron which can be given intravenously. It is the saccharated oxide of iron. Let me emphasize, however, that I advise the oral administration of iron in all instances in which this is possible. Occasionally, however, a patient who cannot tolerate oral iron because it upsets the gastrointestinal tract can be treated successfully with saccharated oxide of iron. A 5 cc. ampule contains 100 mg., and we give 50 mg. (2.5 cc.) the first day slowly intravenously, then 100 mg. in a 5 cc. volume every day thereafter until the total calculated dose is injected. One hundred milligrams of saccharated oxide of iron will raise the hemoglobin in an average adult about 4 per cent. Therefore, if a 40 per cent deficit is present in the hemoglobin of the circulating blood you would give a total dosage of 50 cc. or 1,000 mg. of saccharated oxide of iron over a period of 10 to 14 days in order to bring the hemoglobin to 100 per cent.

This preparation of iron is also useful occasionally in the last trimester of pregnancy when the patient finds it difficult to take the medication by mouth. Parenteral iron is not ordinarily indicated, but when needed it can be given without difficulty if it is injected slowly.—Cyrus C. Sturgis, M.D., Use of Iron Medication, *Postgraduate Medicine*, September, 1953.

ADVANTAGES AND COMPLICATIONS OF TRACHEOTOMY

Hamilton S. Davis, M.D., Henry E. Kretchmer, M.D.
and
Roger Bryce-Smith, B.M., D.A., Cleveland

The possibility of relieving upper respiratory obstruction by a tracheotomy was first discussed by Asclepiades in 124 B.C., but the first authentic operation was probably performed by Brassavola in 1546.[1] Until the middle of the 19th century, it was considered a hazardous procedure and was rarely performed. Even after this time it was still regarded as a last resort for such dire emergencies as might arise in membranous diphtheria, neoplasms of the upper respiratory tract, and, occasionally, injuries of the pharynx, larynx, and trachea. During the last 10 years the operation has been performed more frequently, but still usually as an emergency procedure, and the newer concept of an elective operation has been accepted with reluctance in many quarters. Anesthesiologists have come to recommend this operation more as a prophylactic measure than as an emergency treatment, not only because an airway is assured but, perhaps even more specifically, because it provides an easy route to the lower respiratory tract for aspiration of secretions.

In addition to relieving respiratory obstruction, the value of tracheotomy has recently become apparent in the following conditions: (1) weakness of the respiratory muscles, causing difficulty in removal of secretions by coughing; (2) loss of voluntary control of the airway; and (3) unconsciousness, with an absent or weak cough reflex leading to subsequent atelectasis and pneumonia. We are not alone in having stressed the value of tracheotomy in head injuries[2] and bulbospinal poliomyelitis.[3] We have also advocated its use in various conditions, including certain other diseases of the central nervous system, barbiturate intoxication, acute laryngotracheobronchitis, trauma, and neoplasms affecting the upper respiratory passages.

The fear of disfiguring cosmetic results is uppermost in the minds of many persons. Paradoxically, this objection is rarely listed in the medical literature, perhaps because those who raise the objection realize that a scar is a small price to pay for averting certain death. Other complications, both immediate and postoperative, must be considered as calculated risks.

Severe hemorrhage, technical difficulty with the surgical procedure, pneumothorax, mediastinal emphysema, laceration of the esophagus, massive aspiration of blood, prolonged apnea on the relief of obstruction, and even death have been reported as immediate operative complications. Some of these may be seen during the postoperative period also, but it is often difficult to establish whether they were initiated before or during the operation. In addition, however, the following factors must be listed: secondary hemorrhage, tracheobronchitis, atelectasis, pneumonia, subcutaneous emphysema, obstruction of the tracheal cannula, incorrect size of cannula, glottic stenosis, infection of the wound, hoarseness, and difficulty in extubation.

PRESENT STUDY

In view of this formidable list of complications and hesitancy on the part of some surgeons to perform elective tracheotomy, we thought it wise to study the direct complications and effects of the operation before further encouraging its use in the management of patients with airway problems. We have therefore investigated the records of 155 consecutive tracheotomies performed on 151 patients during the five year period 1948 to 1952 at the University and City hospitals of Cleveland. In this period chemotherapy and the use of antibiotic drugs were well established and minimized at least one source of possible complications. This factor is common to all our cases, and no attempt has been made to compare them with others performed prior to the advent of modern drug therapy.

About half of our tracheotomies were performed in 1952, and we have had personal experience in the management of most of these. For purposes of comparison and evaluation, the series has been divided into six groups according to the disease from which the patient was suffering (table 1).

COSMETIC RESULTS

The cosmetic results could be evaluated in only 56 of the 155 tracheotomies performed. In the remainder, some patients had permanent tracheostomies, some died, and the rest could not be traced or their records were not sufficiently complete to give an adequate evaluation (table 2).

It is encouraging that 84% of those patients who could be checked had good cosmetic results. Of those results classified as poor some might be described more accurately as fair, and included minor keloid formation. A survey of the literature has revealed nothing on this aspect of tracheotomy—except in the case of permanent stomas following total laryngectomy[4]—and therefore we have included our small series. We believe that if such a high proportion have a good cosmetic result, the patient and surgeon alike may gain confidence from this knowledge.

Primary healing is to be expected regardless of how long the tracheotomy tube is left in place. Tracheostomies have been reported that have tended to close spontaneously after 70 years.

Read before the Section on Anesthesiology at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

COMPLICATIONS

Operative Complications.—The operative complications that we encountered in this series are listed in table 3. It is likely that a certain number of complications were not recorded, because they either were not recognized or were of a minor character. The most important hazard met during operation was hemorrhage, which was frequently associated with operative difficulties. To this must be related the skill of the surgeon and the circumstances under which the operation was performed. As might be expected, more complications occurred when the operation was performed as an emergency. In 89 emergency tracheotomies, complications occurred in 26, an incidence of 29.2%. In 66 elective operations, complications occurred in 9, an incidence of 13.7%.

Many factors influenced these figures, including the condition of the patient, the availability of a competent surgeon, the presence of an anesthesiologist or other person capable of maintaining the airway of the patient during the operation, adequate assistance, and operating room facilities. These findings suggest that a tracheotomy should be performed whenever possible as an elective operation under optimum conditions. The few unnecessary tracheotomies resulting from such a philosophy will cause little harm and the results will justify the risk. In retrospect, we are of the opinion that at least 17 of the emergency operations could or should have been performed electively.

Provided an airway is assured before operation, the choice of anesthetic, either local or general, is of secondary importance in most cases. Such an airway may be established by the passage of a bronchoscope or endotracheal tube with the patient under topical anesthesia or without any anesthesia at all in extreme cases. General anesthesia must be forbidden unless the airway can be guaranteed, by intubation if necessary. The importance of this is emphasized by the four deaths that occurred in our series owing to asphyxia due to obstruction unrelieved before the emergency operation was begun. Following intubation, the anesthesiologist can assist the surgeon by correctly positioning the head and by manipulating the endotracheal tube or bronchoscope to assure the airway during the critical time when the cannula is being inserted. In children it is often difficult to recognize structures, and a lighted bronchoscope can indicate the point at which the trachea should be entered.

Proper placing of the tracheal incision may prevent certain postoperative difficulties, for example, in patients who are to be nursed in a tank respirator. The following case is illustrative.

REPORT OF A CASE

A man, aged 28, was suffering from the progressive paralysis of bulbospinal poliomyelitis. He was having difficulty in clearing his airway of secretions, and intercostal weakness made use of the respirator necessary. It was decided to perform a tracheotomy. He was intubated under topical anesthesia, and the operation was carried out with local anesthesia by infiltration. The surgeon, however, miscalculated the point of incision into the trachea and, while thinking he was entering the second and third rings, actually incised the seventh and eighth. On the patient's return to a respirator, it was found almost impossible to adjust the rubber collar in such a way that the tracheotomy opening would lie clear. The makeshift arrangement that became necessary did not give an air-tight fit and increased the nursing problems.

In general, the tracheotomy opening should be as high as possible without risking damage to the cricoid, the usual cause of glottic stenosis.[5] The reverse is probably true in patients suffering from neoplasms of the upper respiratory tract.[6] A previous tracheotomy is not a contraindication to a second. Five of our patients had repeated operations without any difficulty.

Postoperative Complications.—The presence of a foreign body in the trachea, i. e., the cannula, necessarily causes a mild tracheitis and stimulates an increase in secretions. These reactions must be expected but, since they are temporary and do not influence the clinical course significantly, have been omitted from table 4.

Atelectasis, bronchopneumonia, and tracheobronchitis head the list of postoperative complications, but it was known that these conditions existed preoperatively in many cases, a point well recognized in the literature.[7] It was surprising to see how infrequently mediastinal emphysema and pneumothorax occurred, although both have received the greatest prominence in reports. The disparity is difficult to explain but since routine postoperative chest roentgenograms were not made, a number of cases must have been unrecognized.

The mechanisms concerned with the production of mediastinal emphysema and pneumothorax have been investigated by numerous authorities. Since frequent trauma to the domes of the pleura is improbable, only two explanations seem likely. One suggestion is that, as the pretracheal fascia is incised, a potential space is opened through which air is drawn into the mediastinum by the high negative intrathoracic pressure occurring with excessive inspiratory efforts. This later ruptures through the pleura to produce a pneumothorax.[8] The second theory implies a rising alveolar pressure secondary to obstruction, with a series of minute ruptures that allow air to pass interstitially at first, then into the mediastinum, and finally into the pleural cavity.[9] In both cases, abnormal pressures are required, such as are found in the presence of severe upper respiratory obstruction. Since one-third of our patients were suffering from poliomyelitis and therefore were incapable of excessive muscular effort, a possible explanation is offered for the few pneumothoraces seen in our series. It is interesting to speculate whether the pressures produced by a tank respirator are sufficient to produce the necessary trauma to the lungs, even in the presence of extreme respiratory obstruction.

Postoperative hemorrhage may be secondary to infection or failure to establish efficient hemostasis, and the proximity of so many large vessels makes this complication a very real danger. Mechanical erosion of the trachea by the cannula may cause bleeding. Such cases have been reported,[10] and we encountered one in our series.

Although infection of the wound is infrequent and relatively unimportant, such problems as obstruction of the cannula by secretions, blood, and vomitus are serious and can be prevented only by good nursing.

Apnea after relief of obstruction is probably due to sudden lowering of arterial carbon dioxide so that the respiratory center, whose threshold has been elevated, is no longer stimulated. It has also been suggested that the result of an alkali reserve determination in itself may give an indication for performing a tracheotomy in long-standing respiratory obstruction.[11]

COMMENT

From the lists of operative and postoperative complications in the preceding tables, it would appear at first sight that 155 occurred in 155 tracheotomies. This is misleading, since any mishap that occurred, whether or not it was related to the operation, was recorded. Also, there were many instances of multiple complications in the same patient. Table 5, which indicates the number of tracheotomies associated with major and minor complications, is a more accurate representation of the results.

Gross hemorrhage, pneumothorax, and mediastinal emphysema are examples of what were considered major complications; wound infection, slight hemorrhage, and subcutaneous emphysema were considered minor complications. It will be noted that major complications in the emergency group occurred almost twice as frequently as in the elective group. Most of the deaths in the series were not attributable to the tracheotomy, but to the underlying condition. Six deaths were, however, closely related to the operation. Four of these occurred during the procedure and have been mentioned previously; both of the others were due to difficulty in extubation and occurred in the late postoperative period.

TABLE 5.—*Number of Tracheotomies with Complications*

	Elective	Emergency	Total
Operations	66	89	155
Major complications	6 (9%)	14 (16%)	20 (13%)
Minor complications	18	16	34

SPECIAL GROUPS

Patients with laryngotracheitis and poliomyelitis, in addition to providing about half of our series, were the only two groups that could be classified by discrete clinical entities.

Laryngotracheitis.—Most patients with laryngotracheitis are not admitted to the hospital until they are in severe distress, and it is not surprising that all the tracheotomies in this group were performed as emergencies. Even hospitalized patients may deteriorate so rapidly that there can be no choice, but if elective operation is possible, then the criteria of Briggs and Heseltine[12] should be followed; the indications are (1) cyanosis, (2) restlessness, and (3) progressive fatigue. The last indication is frequently not appreciated but is as real as the others, and is applicable not only to laryngotracheitis but to any other condition involving respiratory obstruction or accumulated secretions.

Poliomyelitis.—In the poliomyelitis group, no tracheotomies were performed before 1949, but thereafter they were performed with increasing frequency, with a swing from emergency to elective operations (table 6).

The decision to perform an elective tracheotomy depends on the site and progression of paralysis. Severe bulbar involvement is now well established as an indication for the operation, but a rapidly falling vital capacity is in itself a good indication.[13] Although at first sight this suggests merely intercostal weakness, it also implies an ineffective cough and, therefore, an inability to remove secretions in a patient who will probably need respirator care. Further, we are coming to believe that any patient who is desperately ill and must be nursed in the respirator should receive a tracheotomy, even though other specific indications are absent.

SUMMARY

A total of 155 tracheotomies were studied to determine the incidence and severity of complications during and following the procedure. Although a total of 155 related complications were encountered, these occurred in 54 tracheotomies. In these 54 tracheotomies, major complications were seen in 20, 14 of which were emergencies. Elective tracheotomy, after the provision of an airway, reduces the number of serious complications and is to be preferred to emergency operation whenever possible. The high incidence of complications must be considered in relation to the gravity of the patient's condition, with asphyxia and probably death as an alternative. The cosmetic results were generally good and should never influence the decision to perform the operation. Tracheotomies should be recommended whenever the patient's ability to maintain an airway or remove secretions is seriously impaired.

ROLE OF ANTICHOLINERGIC DRUGS IN TREATMENT OF PEPTIC ULCER

and
G. J. Baylin, M.D., Durham, N. C.

The anticholinergic drugs are compounds that have been introduced recently into clinical medicine. As with other new agents that have been employed in the past in the treatment of peptic ulcer, the initial reports of the value of these drugs were glowing with enthusiasm. It was stated that one of these compounds, methantheline (Banthine), was so effective as the sole treatment of ulcer that conventional medical management was no longer necessary, that recurrences could be prevented, and that the need for surgery was obviated.[1] Many of these studies, however, were not controlled, and it is difficult to determine whether the beneficial effects attributed to the drug were actually produced by it. Recent investigations, more critically conducted, have failed to confirm some of the original observations, and, as a result, considerable confusion exists in the profession as to the exact value of these agents. The purpose of this paper is to summarize present-day knowledge in an effort to clarify the role of the anticholinergic drugs in the treatment of peptic ulcer.

PHARMACOLOGY

The cholinergic blocking agents currently available include methantheline (Banthine), diphenmethanil (Prantal), oxyphenonium bromide (Antrenyl), and propantheline bromide (ProBanthine). A large number of similar compounds are under investigation at the present time. It is beyond the scope of this paper to attempt a comparative evaluation of these compounds.

These drugs interfere with the cholinergic transmission of nerve impulses and differ from the atropine group in that they are effective not only at the effector site but also at the parasympathetic ganglions. This blockade of parasympathetic impulses results in a so-called "medical vagotomy" with inhibition of both secretory and motor activity of the stomach. In addition to these effects, Wolf has observed a decrease in engorgement of the gastric mucous membrane after their administration.[2] In higher dosage, there is some evidence of sympathetic ganglionic block of motor nerves and a curare-like action.

Adverse side-effects include atropine-like visual and salivary disturbances, tachycardia, difficulty in urination, abdominal distention, constipation and an ill-defined feeling of lassitude or fatigue. Dermatitis and stomatitis occasionally follow their administration.

EFFECT ON GASTRIC SECRETION

It is generally agreed that the anticholinergic drugs inhibit gastric secretory activity with a reduction in both

volume and acidity.[3] The response following oral administration in each patient is both variable and unpredictable, and anacidity is not often attained with currently available drugs unless high doses are employed. After parenteral administration, anacidity occurs more frequently. Unlike vagotomy, these drugs have little effect on the cephalic phase of gastric secretion.[4] The duration of the antisecretory effect of these drugs is likewise variable, lasting from 30 minutes to several hours. Potent antisecretory activity usually is accompanied by profound side-effects. There is no convincing evidence of cumulative action or of the development of tolerance after prolonged administration.

EFFECT ON GASTROINTESTINAL MOTILITY

The effect on gastrointestinal motor activity is generally more pronounced and less variable than on secretion.[5] In the normal person there is no demonstrable effect on the motility of the esophagus as determined by roentgenography; however, balloon studies [6] have demonstrated a reduction in spontaneous motility of the esophagus after methantheline is given intravenously. This agent does not relax the cardiac sphincter or accelerate the passage of barium into the stomach. Administration of these drugs to patients with cardiospasm aggravates the condition, as does vagotomy.[7] Gastric motor activity is greatly altered after parenteral administration; there is marked delay in emptying and cessation of peristalsis for a variable period of time. Propulsive and segmental activity of the small bowel usually is abolished. The results of oral administration are less striking. There is no significant effect of these drugs on the motor activity of the colon as observed by roentgenography, although balloon studies have demonstrated some reduction in peristalsis.[8]

USE IN PEPTIC ULCER

Active Phase.—These drugs, in conjunction with conventional ulcer therapy, are highly effective in many ambulatory patients with an active ulcer. Their administration is usually followed by prompt relief of ulcer distress. The following case report illustrates the effectiveness of the anticholinergic drugs when given orally.

A 59-year-old Negro man gave a history of typical intermittent ulcer pain for 10 years. Despite strict dietary therapy antacids, sedation, and belladonna, his pain continued an radiated to the back. Roentgenograms revealed a marke deformity of the duodenal bulb, with a crater in the posterio wall. Hospitalization was not possible, and the patient wa given propantheline, 30 mg. orally, before meals and at bec time in addition to conventional therapy. One week later h was symptom-free, and during the ensuing six months he ha no recurrence of ulcer distress.

A number of patients, however, are not relieved o their pain in spite of increased oral dosage, and hospita ization is required. In such cases, parenteral administra tion of anticholinergic agents frequently is followed b prompt relief of ulcer distress. Pain can be relieved ofte within a few minutes by injecting them intramuscularl and almost instantly by giving them intravenousl Furthermore, recurrence of pain frequently is prevente by intramuscular injection every six hours over a perio of several days. The next case report is typical of th response to anticholinergic drugs given parenterall when oral administration is ineffective.

A 19-year-old white boy gave a history of recurrent attack of ulcer distress for the preceding five years. A roentgenogra revealed a marked deformity of the duodenal bulb, with suspicious crater. Hospitalization was not possible; therefore a strict diet, antacids, sedation, and bed rest were prescribed In addition, propantheline, 30 mg., was given orally befor meals and at bedtime. One week later, the patient was stil complaining of severe epigastric pain with radiation to th back. Two or three minutes after intravenous injection o 20 mg. of propantheline, the patient's pain was completel relieved and did not recur during the succeeding period o hospitalization while he was receiving propantheline, 20 m intramuscularly, every six hours.

A small number of patients fail to respond to conventional therapy supplemented by either oral or parentera administration of anticholinergic drugs. Usually suc patients have a perforated walled-off ulcer, and prolonge conservative management is of little value. Once th diagnosis of walled-off perforation has been made, subtotal resection should be performed without delay. Th failure of these drugs in a patient having a walled-o perforation is illustrated by the next case report.

A 53-year-old white woman gave a history of recurren attacks of ulcer pain for 12 years. Perforations occurred i 1944, 1945, and 1946. A gastroenterostomy was performe in 1945 and a subtotal gastric resection in 1946. Epigastri pain recurred despite a transthoracic vagotomy in 1947. A marginal ulcer was demonstrated on repeated occasions. I 1953, the patient again was hospitalized because of a sever recurrence that did not respond to conventional therapy. Anticholinergic drugs were given parenterally over a period o several days with little effect. At operation a marginal ulcer with a walled-off perforation adherent to the anterior abdominal wall, was found.

Quiescent or Interim Phase.—The role of these drug in the long-term management of ulcer is still controversial. Only a few carefully controlled studies of thei effect on the course of the disease have been carried out. In order to determine what effect one of these agent might have on the incidence of recurrences and on th development of complications, a controlled clinica study, in which neither physician nor patient knew th identity of the drug prescribed, was undertaken recently.[10] One hundred milligrams of methantheline o 0.4 mg. of atropine were given four times daily to alternate patients as adjuncts to conventional therapy. Two hundred fifty patients were followed for a mean period of 13 months.

Those patients taking methantheline had significantly fewer and milder recurrences than those taking atropine; however, the incidence of recurrences was high in both groups—75% in those taking methantheline and 90% in those taking atropine. It was found that those patients whose symptoms were classified as being mild prior to beginning the study had no recurrences while taking methantheline, whereas in those with severe symptoms the incidence of recurrences was essentially the same in both groups. In spite of the frequency of recurrences in both groups, 75% of those patients taking methantheline had good results as compared with 57% of those taking atropine.

Despite greater symptomatic relief while taking methantheline, the development of complications (hemorrhage, perforation, or obstruction) and the number of patients requiring surgery were essentially the same in both groups. From these studies it was concluded that the eventual course of the disease was not altered significantly by the administration of methantheline, although symptomatic improvement usually occurred while the patient was taking the drug.

Complications of Ulcer.—The role of these drugs in the treatment of two of the complications of ulcer, hemorrhage and obstruction, is also controversial. There is little, if any, published data on this subject. Some feel that reduction in acidity and motility is desirable in patients with active bleeding, while others believe that lack of tone and dilatation of the stomach are detrimental. There is no evidence that these drugs alter the clotting mechanism.[10] Likewise, in patients with obstruction reduction in acidity and spasm is thought to be beneficial; on the other hand, paralysis of the stomach might make complete a previously partial obstruction.

In our experience, no rules can be laid down that apply to all cases, and each patient must be evaluated individually. To illustrate, patients with mild hemorrhage usually recover with conventional medical management alone, and the anticholinergic drugs are unnecessary. In moderately severe hemorrhage, these agents may be used parenterally, provided immediate surgery is not contemplated and constant gastric suction is employed. In massive hemorrhage, either with or without shock, the likelihood of surgical intervention contraindicates their use. Patients with partial gastric retention, especially that associated with spasm due to active ulcer, are frequently benefited by these drugs. In severer retention, however, abolition of peristalsis usually aggravates the condition. Obvious pyloric stenosis due to scarring is a definite contraindication to their use. It is generally agreed that these drugs are contraindicated in perforation into the free peritoneal cavity.

In any patient in whom abdominal surgery is contemplated, these drugs should not be used during the immediate preoperative period because of dilatation and paralysis of the stomach and small intestine. For the same reason their use is contraindicated in the postoperative period. Furthermore, the drugs should not be used immediately preceding roentgenologic study of the upper gastrointestinal tract because the roentgenologist will have great difficulty in interpreting his findings properly in a partially paralyzed stomach.

COMMENT

With the advent of the anticholinergic drugs, the profession has at its disposal for the first time agents that are effective in reducing both secretory and motor activity of the stomach. These drugs have been proved extremely useful as adjuncts to conventional management of active peptic ulcer, whether duodenal, gastric, or marginal. Their most striking clinical effect is the relief of ulcer pain, which is frequently dramatic after parenteral administration. It is of interest to note that this relief of pain is synchronous with cessation of gastric motility despite artificially produced high acid values.[11] Relief of pain, however, is not necessarily indicative of healing as ulcer craters have been observed to persist for weeks or months under treatment even though the patient was symptom-free. There are no accurate data on the effect of these drugs on the healing time of ulcer. In fact, measurement of the healing time in duodenal ulcer is so difficult that it is doubtful that such data can be obtained.[12] These agents have been disappointing in the long-term management of ulcer, since recurrences are not prevented and the incidence of complications or the need for surgery are not significantly altered by their prolonged administration. It should be emphasized that these drugs are not necessary in the management of the simple, uncomplicated ulcer.

It is to be hoped that more effective compounds will be developed that will enable physicians to control more satisfactorily, if not to prevent, the recurrences and complications of peptic ulcer.

Protecting the Farmer from Poisonous Dusts.—Fungicidal dusts containing organic mercury compounds are widely used in agriculture, particularly as seed disinfectants to prevent the smut diseases of cereals. For many years mercurial derivatives of the phenyl and tolyl series have been manufactured without any mishaps worse than an occasional burn on the skin. However in 1940 it was found that poisoning by inhalation of a compound of the methyl series affects the nervous system in a unique manner. The typical signs of mercurialism are not found. There are severe generalized ataxia, dysarthria, and a gross constriction of the fields of vision, memory and intelligence remaining unaffected. In severe cases the patients are permanently crippled and unable to stand or to speak intelligibly. In the manufacture of organic mercury compounds, elaborate precautions must be taken to prevent either contact with the skin or inhalation. The use of gloves and respirators is not enough. The whole process of manufacture, including the final packing of the dusts, must be carried out mechanically in closed apparatus. The lower alkyl mercury compounds should never be made or handled. The farmer should be protected both by warnings that mercurial dressings are poisonous and by schemes whereby he can obtain seed already dressed.—D. Hunter, M.D., Occupational Diseases with Neurological Symptoms and Signs, *The Practitioner,* July, 1953.

HUMAN BRUCELLOSIS CAUSED BY BRUCELLA ABORTUS, STRAIN 19

Wesley W. Spink, M.D.
and
Hugh Thompson, M.D., Minneapolis

In 1923, Buck[1] isolated a virulent culture of Brucella abortus from the milk of a cow. This culture, after standing at room temperature for a year, remained smooth, and although its virulence was considerably reduced, its antigenic properties were retained. After hundreds of subcultures and passages through animals, the original virulence of this strain has not been regained. Because of these stable characteristics, the Bureau of Animal Industry of the United States Department of Agriculture has successfully encouraged the use of strain 19 for immunization of cattle against brucellosis. Persistent infections in animals have not been established in this manner.[2]

The question has often arisen as to whether humans are ever infected by strain 19. No evidence has ever been presented to show that persons have contracted brucellosis from cattle as a result of vaccination with this strain. Gilman,[3] however, has put forth a cautionary note for those handling the vaccine by stating "that Strain 19, is under certain conditions, capable of infecting humans." He cited the instance of a student in veterinary medicine who became accidentally infected after entrance of the organisms into the mucous membrane of the eye while he was vaccinating a calf. As far as we know, this is the only recorded instance in which evidence indicates that a human infection was caused by strain 19. For this reason, we are reporting two cases of brucellosis that occurred in veterinarians who were immunizing calves. While the organism was not recovered from the first patient, the evidence indicates quite clearly that strain 19 was the cause of his illness. The second man was infected under circumstances similar to those in Gilman's case; entrance into the body was through the mucous membrane of the eye while a calf was being vaccinated. Brucella organisms isolated from the patient's blood had characteristics compatible with those of strain 19.

REPORT OF CASES

CASE 1.—A 25-year-old married white veterinarian was vaccinating calves on June 6, 1950. During the course of his work, he dropped the needle and syringe on the ground at 1:00 p. m., and, when he picked up the syringe, the needle accidentally entered the palm of his right hand. At 7:00 p. m. that evening, his hand became swollen, painful, and tender. At 11:00 p. m., he took 250 mg. of chlortetracycline (aureomycin) by mouth. He had a restless night. By morning his temperature was 102 F, and he had chills and generalized body aches. He took two more doses of chlortetracycline, 250 mg. each, four hours apart. His physician then recommended hospitalization.

There were several points in the history of this man that contributed to an understanding of the pathogenesis of his illness. For several months he had had a chronic skin eruption, particularly on his arms, that involved the hair follicles. The lesions presented small reddened areas of suppuration. He noted that whenever blood from a cow with brucellosis contaminated his hands and arms there was a marked accentuation of the rash. In August, 1949, he had had a Brucella agglutinin titer of 1:80, and in November, 1949, a titer of 1:160, which indicated an inapparent Brucella infection. The flaring of the rash on his arms when brought into contact with blood from infected cows indicated a state of hypersensitivity to Brucella antigen, a condition common to veterinarians as pointed out by Huddleson.[4] Furthermore, he stated that about one and one-half years before his present illness, he had a similar accident when the needle on a syringe, which contained viable organisms of strain 19, entered his foot. At that time he had a localized reaction but no systemic complaints.

On admission to the hospital, approximately 24 hours after the accident, the man's temperature was 102.2 F and pulse rate 88 per minute. He appeared toxic with a hot and flushed face. There were no abnormal physical findings except a folliculitis of the upper part of the arms and chest. There was a puncture wound in the palm of the right hand between the bases of the third and fourth fingers. The hand was swollen and tender. The right forearm displayed lymphangitis, with tenderness along the flexor surface. The axillary nodes on the right side were enlarged and tender. The initial laboratory data revealed a normal urine analysis. The hemoglobin was 14.1 gm. per 100 cc., and the total leukocyte count was 6,850 per cubic millimeter, with 89% polymorphonuclear neutrophils and 11% lymphocytes. The erythrocyte sedimentation rate was normal. Agglutinins for Brucella were present in a titer of 1:160, and an initial blood culture remained sterile. The man was treated with chlortetracycline; he received 500 mg. four times daily. Hot packs were applied to the right hand. His clinical course is outlined in figure 1. During the first 36 hours, illness was marked by shaking chills and fever. On the third day, the patient felt much better, but the right middle finger was tender and movement of the digit was painful. He continued to improve, and he went home on the ninth day. He continued to take chlortetracycline for a total of 21 days. Except for a small amount of swelling of the right middle finger and limitation of motion, there were no residuals of the illness at the time the man was discharged from the hospital.

In summary, this is the case of a man who had been previously exposed to brucellosis. Evidences for this exposure were the presence of Brucella agglutinins in his blood and the marked state of hypersensitivity to Brucella antigen. The introduction of strain 19 into his hand resulted in both localized and systemic reactions. It is not known whether the man's blood stream was invaded by viable Brucella because cultures remained sterile. It should be remembered that chlortetracycline was administered before specimens of blood were obtained for culture. The type of illness observed in this man is not uncommon and is seen oftenest in persons in whom Brucella antigen has been injected for diagnostic or therapeutic purposes. It is a manifestation of tissue hypersensitivity to Brucella antigen. Persons repeatedly exposed to Brucella, such as veterinarians and laboratory workers, are most likely to display this type of illness.

CASE 2.—A 25-year-old, unmarried, white student of veterinary medicine was in an excellent state of health prior to his illness. During the latter part of March, 1953, he secured temporary work with a veterinarian immunizing calves with strain 19. Eight days before the onset of his illness, the student

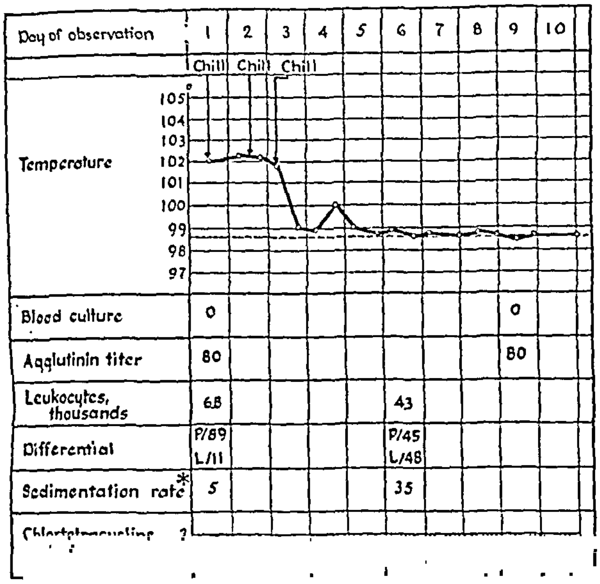
was vaccinating a calf in the caudal region. He was using a lyophilized preparation of strain 19 that had been reconstituted in 6 ml. of solution. According to the standards of the Bureau of Animal Industry, under which this material is marketed, the suspension contained a minimum of 10 billion viable organisms per milliliter. While bending over in an attempt to inject a portion of the suspension into the subcutaneous tissue of the animal, an obstruction to the flow through the needle was encountered, and, because of back pressure, "most of the suspended organisms" contained in the syringe were splashed into both eyes. No inflammatory reaction of the ocular tissues ensued, and the student suffered no ill effects until eight days later when pain in the muscles occurred and was followed by frontal headaches, chills, and fever. He became progressively worse, and 11 days after the onset of the illness he entered the hospital.



* Millimeters per hour, Westergren

Fig. 1.—Clinical course of patient (case 1) with brucellosis caused by Brucella abortus, strain 19.

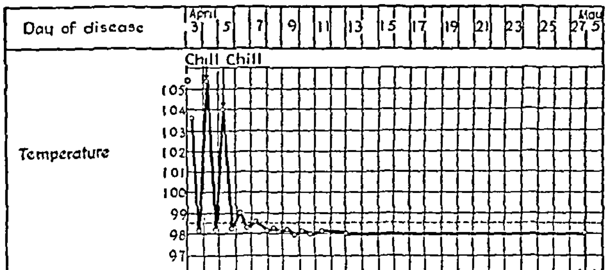
Of particular interest in this patient's history is the fact that he had always enjoyed good health. It was known that he did not have Brucella agglutinins in his blood prior to this illness. When he entered the hospital he was quite ill and exhibited evidence of severe toxemia. His outstanding complaints were marked weakness and rigors followed by fever. He had generalized body aches, with severe occipital headache and pain over the lumbar area. He was anorexic and restless.

Physical examination revealed a temperature of 103 F; pulse, 100; and blood pressure, 130/70 mm. Hg. His skin was warm and moist. No lymphadenopathy was present. The eyes appeared normal. The only physical abnormality noted was an enlarged and tender spleen palpated 2 cm. below the left costal margin. There was pain on percussion over the lumbar spine. The urine analysis was normal. The hemoglobin level was 16.2 gm. per 100 cc. The leukocyte count was 5,700 per cubic milliliter, with 87% polymorphonuclear neutrophils, 11% lymphocytes, and 2% monocytes. The erythrocyte sedimentation rate was normal. During the first 48 hours after admission, eight specimens of venous blood were cultured in Albimi Brucella broth. From one of these cultures, an organism compatible with Br. abortus, strain 19, was isolated. The initial Brucella agglutinin titer was 1:320. A skin test done with brucellergen elicited a mild localized reaction.

The patient's clinical course is presented in figure 2. He had severe episodes of chills, and on the second day his temperature was over 105 F. Because of the seriousness of his illness, treatment was initiated with 0.5 gm. of dihydrostreptomycin given intramuscularly twice daily and 0.5 gm. of chlortetracycline administered orally four times a day. Within 24 hours his temperature dropped to normal, and within 72 hours he felt much better. He progressively improved, and on the fourth day of treatment his appetite had returned. After seven days of treatment the administration of dihydrostreptomycin was discontinued. Chlortetracycline was continued, however, and was given for a total of 21 days. It should be noted that, on the ninth day after admission, the patient's Brucella agglutinin titer was 1:2,560 and that blood cultures remained sterile. Except for some slight residual weakness when he left the hospital after a stay of 11 days, the patient had recovered. When seen one and two months later, he was completely recovered. His agglutinin titer was 1:1,280 one month and 1:320 two months after discharge.

BACTERIOLOGICAL IDENTIFICATION

In view of the exposure of the patient in case 2 to Br. abortus, strain 19, extensive studies were carried out on the culture obtained from his blood. The primary culture was acquired in Albimi Brucella broth [5] contained in a bottle to which 10% carbon dioxide had been added. The first subculture grew aerobically, which is extremely unusual in our laboratory for freshly isolated strains of Br. abortus. A Gram stain of the culture revealed the characteristic gram-negative coccobacillary forms. The initial culture consisted of smooth colonies. A suspension in 0.85% sodium chloride solution was agglutinated by antibrucella rabbit serum. On dye plates, growth took place in the presence of basic fuchsin, but thionine inhibited growth. These observations indicated that the culture contained Br. abortus, and the fact that the first subculture grew freely without added carbon dioxide suggested that this was a culture of Br. abortus, strain 19.



* Millimeters per hour, Westergren

Fig. 2.—Clinical course of patient (case 2) with brucellosis caused by Brucella abortus, strain 19. Note that an initial culture of blood yielded Brucella organisms.

Comparative studies were then made with three virulent strains of Br. abortus previously isolated from patients. The strains are known in this laboratory as 1,

---

[5] The Albimi Brucella broth was supplied by Albimi Laboratories, Inc., 16 Clinton St., Brooklyn, N. Y.

Lynch 524, and El 9-28. The latter strain was isolated from a patient with subacute bacterial endocarditis. The standard culture of strain 19 was obtained from the Bureau of Animal Industry, and a lyophilized culture of strain 19 was studied that was similar to the one used by the patient while attempting to immunize a calf.[6] The strain isolated from the blood of the patient is known as 2068 in our laboratory. The results of these investigations with these strains are presented in the table. It is to be noted that the three virulent strains of Br. abortus did not reproduce under aerobic conditions but that they required addition of carbon dioxide, which is in contrast to the two cultures of strain 19, and strain 2068 isolated from the patient. The virulent strains grew abundantly on agar plates containing from 0.2 to 0.6 mg. per milliliter of thionine blue [7] or methylene blue. The growth of two cultures of strain 19 and that of strain 2068 was, on the other hand, inhibited in all of the concentrations of dyes. Comparative virulence studies were carried out in guinea pigs using an inoculum of 1 million organisms from a culture that had been grown for 48 hours on Albimi Brucella agar. The bacterial suspensions were injected intraperitoneally into male guinea pigs, and the animals were killed six weeks later. None of the animals appeared ill when killed. As shown in the table, there was evidence that an infection was established in animals receiving the virulent cultures, Lynch 524 and El 9-28. Brucella agglutinins were demonstrated in the serum, and either lesions were seen or Brucella were recovered from the tissues. Animals that received strain 19 and strain 2068 displayed no evidence of an infection. In a second type of virulence study to be reported in detail elsewhere, a suspension of 10 billion organisms was injected intravenously into white mice. Under these circumstances the virulent strains of Br. abortus caused death within 24 hours, whereas strains 19 and 2068 were less lethal; the mice succumbed only in three to seven days.

Comparative Studies with Virulent Cultures of Brucella Abortus, Cultures of Strain 19, and the Strain Isolated from the Patient in Case 2 (Strain 2068)

			Inhibition of Growth by Dyes (0.2 to 0.6 Mg./Ml.)		Virulence Studies	
Strain	Source	Growth Under Aerobic Conditions	Thionine Blue	Methylene Blue	In Guinea Pigs	In Mice
1	Human	Failed to grow; required added CO_2	None	None	....	....
Lynch 524	Human	Failed to grow; required added CO_2	None	None	1:40 agglutinins; Brucella recovered from spleen	Caused death in 24 hr.
El 9-28	Human	Failed to grow; required added CO_2	None	None	1:2,560 agglutinins; granulomas in liver	Caused death in 24 hr.
19	Bureau of Animal Industry	*Grew abundantly*	Complete	Complete	*No agglutinins or lesions* and no recovery of organisms	Caused death in 3-5 days
19 Lyophilized	Pitman-Moore Co.	Grew abundantly	Complete	Complete	....	....
2068	Human	Grew abundantly	Complete	Complete	No agglutinins or lesions and no recovery of organisms	Caused death in 3-7 days

These investigations revealed that the strain of Br. abortus isolated from the blood of the patient possessed the characteristics of strain 19. The culture was smooth and growth took place readily under aerobic conditions, but the organisms did not reproduce in the presence of thionine blue and methylene blue. Studies in guinea pigs and mice demonstrated reduced virulence when compared to strains of Br. abortus isolated from human subjects.

Because it was highly desirable that the identity of this strain be determined in other laboratories, subcultures were submitted to two competent persons who have had considerable experience in differentiating the dissociates of Brucella organisms. Dr. Norman B. McCullough, chief of the Laboratory of Clinical Investigation in the National Microbiological Institute, Bethesda, Md., kindly studied this strain and then submitted the following report: "Prior to making our observations with Brucella abortus culture 2068, we isolated the nearest to smooth phase represented in the culture. From a morphological standpoint, I would classify this phase as an early intermediate, that is Huddleson's SI_1. We were unable to recover an S phase from the culture. In comparison with Strain 19, this culture exhibits a similar dissociation pattern. Furthermore, we inoculated Strain 19 and Strain 2068 into guinea pigs using three different dosages and three animals for each level. Both Strain 19 and Strain 2068 were recovered from the tissues of guinea pigs at the dosage level of one million organisms but not at one thousand. Strain 2068 failed to produce evidence of gross pathology with any of the dosage levels. From our studies then, culture 2068 has the same infectivity as Strain 19 for guinea pigs. It is like Strain 19 in that it is not a smooth, but an intermediate colony type, and exhibits the same dissociation pattern as Strain 19. These data coupled with the studies which you have already done, would seem to me to identify your culture as presumably Strain 19, as well as one will ever be able to do. All of the data are in accord with the hypothesis that this is Strain 19. No data are contradictory."

Dr. C. A. Manthei, head of the Section on Bacterial and Mycotic Diseases in the Animal Disease Station of the Agricultural Research Center, Beltsville, Md., also kindly studied this culture and stated: "According to our tests, the culture is a strain of Brucella abortus that did not require CO_2 for growth. Tests for virulence were conducted in guinea pigs and on tryptose agar plates containing various concentrations of thionine blue. The latter tests indicate that the virulence of Strain 2068 is similar to that of Strain 19. It is impossible to make a more positive statement because there are no tests at the present time that will unconditionally identify Strain 19."

---

[6] The Brucella abortus (B. A. I. Strain 19) organisms were supplied by Dr. R. V. Johnston, Pitman-Moore Company, Indianapolis.

[7] McLeod, D. H.: The Use of Thionine Blue for the Identification of *Brucella Abortus, Strain 19, J. Comp. Path. & Therap.* **54**: 248, 1944.

In summary, this patient had a demonstrable bacteremia due to Br. abortus. Subsequent studies of the causative organism indicated that it was Br. abortus, strain 19. In contrast with the illness in case 1, the genesis of this patient's illness could not be ascribed to a state of hypersensitivity, since no ocular reaction followed the introduction of large numbers of organisms into the eye, and a skin test with brucellergen yielded only a mild, local reaction. Investigations now in progress indicate that the patient's illness was associated with endotoxin liberated by strain 19. This endotoxin is found in common with the more virulent strains of Br. abortus, and comparative studies in animals show that, under certain circumstances, the endotoxin from strain 19 is just as lethal as the endotoxin from the more invasive strains. These observations suggest that, given the proper host in which strain 19 can reproduce, illness will result because of the liberation of endotoxin. This mechanism is being investigated further in experimental animals.

COMMENT

An effective means for immunizing cattle against brucellosis involves the infection of viable organisms of Br. abortus, strain 19. In the campaign to eradicate bovine brucellosis, strain 19 is being used extensively in the United States and in other countries where Bang's disease is a problem. This report on human brucellosis caused by strain 19 does not imply in any way that the use of this vaccine should be curtailed. It does emphasize, however, that strain 19 is not innocuous and that it should be handled only by qualified persons, preferably veterinarians, and then with the knowledge that the accidental introduction of the organisms into the human subject may be followed by illness.

SUMMARY AND CONCLUSIONS

Two veterinarians became ill after the accidental introduction of Brucella abortus, strain 19, into their tissues. In one, the illness was associated with marked hypersensitivity to Brucella. The organism was isolated from the blood stream of one of the patients who was quite ill with brucellosis, and the organism was identified as Br. abortus, strain 19. This is the first recorded instance in which such bacteriological proof has been accumulated and that shows that human brucellosis can be induced by strain 19. This report does not call for the restriction of immunization programs for bovine brucellosis but emphasizes that strain 19 should be employed cautiously and only by properly qualified persons.

RECURRENT ANAL FISSURE

CONCEPT OF PATHOGENESIS AND TREATMENT

Guy L. Kratzer, M.D., Allentown, Pa.

Chronic anal fissure represents one of the most painful diseases occurring in the anorectal area. Cure requires removal of all abnormal tissue and is primarily a surgical problem. Proper correction results in dramatic relief. The surgeon learns early in his career that some of the most grateful patients are those who have been successfully operated on for chronic anal fissure. The majority of these patients remain well. A significant number suffer from recurrence. It is for this reason that the present study was undertaken.

DEFINITION OF PROBLEM

A fissure is a slit-like elongated ulcer at or near the anorectal line. It is commoner in men than in women. It occurs during the active years of life and is most commonly found in the posterior portion of the anal canal. Recurrence, after all forms of treatment and particularly after medical management and some forms of surgical treatment, is frequent enough to warrant a review of the etiology and pathogenesis of fissure.

Removal of the ulcer alone will not result in a high enough incidence of cure. An attempt at removal of the cause must be made. The problem in theory is analogous to the surgical management of duodenal ulcer.

During the past decade, occasional recurrence of fissures was noted. These recurrences were noted in patients who had been subjected to injection therapy, anal dilatation alone, or anal dilatation combined with limited surgery or excision of the ulcer without removal of the associated disease process. The patients in this category were treated in the physician's office or the hospital. None of the patients in this group with recurrences were subjected to a complete rectal operation, that is, removal of all associated abnormal tissue, such as crypts, papillae, and hemorrhoids. This aroused interest and an attempt was made to explain the higher incidence of recurrence of fissures following the limited types of surgery than in those including more complete eradication of abnormal tissue.

PRESENT KNOWLEDGE

A review of our present concept of fissure is justified. The investigation concerns chronic anal fissure only and is not concerned with the acute fissure or break in the anal skin that occurs from trauma instituted by hard stool or other foreign body. These lesions heal spontaneously unless the causative trauma is repeated indefinitely.

The classic description of the abnormality indicates that an anal fissure is a superficial ulcer, with thin edges and a smooth base that may be either pink or red. Furthermore, the commonly accepted theory suggests that, after the original ulcer or break in the skin occurs, the fecal discharges initiate a chronic inflammatory process

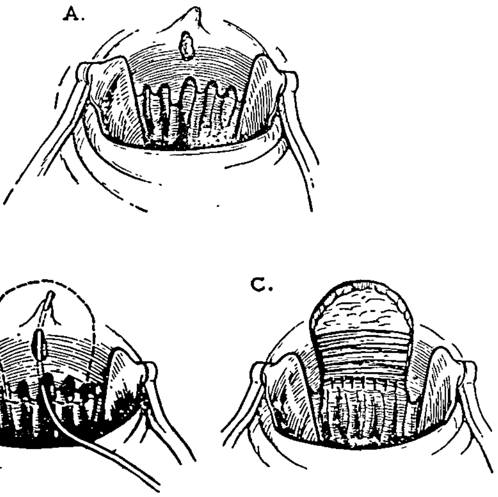
Read before the Section on Gastroenterology and Proctology at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

with resultant edema and reaction that eventually result in the elongated sentinal pile and fibrous papilla; hence the classic triad of sentinal pile, ulcer, and papilla. The commonly accepted causes of fissure are (1) angulation of posterior rectal wall with anal canal, (2) subcutaneous sphincter constitutes a bar, (3) first part of the anal sphincter lacks support and allows trauma to skin, (4) lack of firm support anteriorly in women, (5) failure of the second portion of the anal sphincter to decussate posteriorly, and (6) faulty anal hygiene and poor bowel habits.

The three commonest complications of fissure, according to classic knowledge, are formation of a subcutaneous abscess with formation of a blind or incomplete fistula, anal contraction, and constipation with all its associated ills.

INVESTIGATION

On the basis of a liberal experience, the statement may be made that one may remove, in a given case, all heretofore described pathological tissue, dilate the sphincter, incise or excise a portion of the sphincter, and in every way follow the teaching of previous years and still have a comparatively high recurrence rate of fissures. The conclusion to be drawn, then, is that some causative factor or pathological process has been overlooked.



A, appearance of typical anal fissure; *B*, fissure associated with fistula; and, *C*, wound after removal of diseased tissue.

It is not claimed that anything new has been added to the literature; however, a few pertinent observations are recorded. On numerous occasions during surgery, the presence of a fistula associated with fissure was noted. The primary opening occurred in a crypt, one secondary opening occurred at the site of the fissure, and another secondary opening occurred on the skin at a distance beyond the fissure. This immediately posed the question as to the possibility of whether the fissure might merely be a manifestation of a fistula. This observation suggests that something in addition to simple ulcer is involved. The analogy of pathogenesis of fistula and fissure is definitely suggested. This observation suggests the necessity of a search for a disease process that is not obvious on gross examination.

It is the exception rather than the rule that patients with anal fissure will need surgery only for this entity Invariably, when one makes a thorough examination during the surgical operation, other abnormalities, such as infected crypts, enlarged anal papillae, hemorrhoids anal contraction, skin tags, abscesses, or other evidences of infection, will be observed. Of all these abnormalities none seems to be so prominent as infection of the crypts Although a frank fistula, which may be probed, is no always observed, the crypts frequently present evidence of infection, such as hyperemia, exudation, or unusua penetration. This suggested the possibility that microscopic examination might clarify the problem.

In 1947, Dockerty and I,[1] reported the results of an investigation to determine the presence or absence of ana ducts in the human, their nature, their relative position in the various areas of the anal canal, and their possible relationship to disease of the terminal bowel and its adjacent structures. These microscopic tubules communicate with the anal crypts and may extend into or through the sphincter muscle. There are seldom more than six or eight of these ducts. Their lining consists chiefly of several layers of polygonal cells, but the ampullae and branches are lined with one or two layers of cuboidal cells. They are most commonly found in the posterior portion of the anal canal. In a limited study of human embryos, their incidence was slightly greater in the male than in the female embryos.

In a previous study of 100 anal crypts, it was noted that in practically every instance in which cryptitis was found there was also associated inflammatory reaction about the ducts. This observation stimulated further investigation and accordingly several hundred slides made from tissue taken at the time of operation from patients with gross evidence of disease involving one or more anal crypts were studied. Those that did not show ducts were eliminated. The slides showing ducts were investigated to determine the presence or absence of cryptitis and inflammatory reaction of the ducts themselves. Obviously these sections were in a selected group since each one to be included in this study had to show the crypt with a portion of rectal mucosa above and anal skin below and the underlining tissue containing the ducts. This group consisted of 24 sections.

The term cryptitis indicates a diagnosis of a pathological condition that is made microscopically. To be so designated, the crypt must show unusual infiltration of the tissue with polymorphonucular leukocytes, plasma cells, lymphocytes, or a combination of these cells. In the chronic forms, fibrous tissue is usually an associated finding. In this study it was possible to designate each case of cryptitis as an acute, subacute, or chronic process. Of these 24 cases, 9 showed definite cryptitis. Of the nine, eight showed evidence of periductal inflammation. Only two cases showed periductal inflammation without apparent disease of the crypts. One case in the series showed the presence of cryptitis and polymorphonucular leukocytes in the lumen of the duct without apparent periductal inflammatory reaction. Normal ducts did not show such a collection of cells. It was not difficult to distinguish the normal duct from the abnormal one. Similarly, it was not difficult to distinguish the normal crypt from one involved in an inflammatory process.

---

[1] Kratzer, G. L., and Dockerty, M. B.: Histopathology of the Anal Ducts, Surg., Gynec. & Obst. 84: 333-338 (March) 1947.

METHOD OF INVESTIGATION

The frequent association of fissure with cryptitis manifested by gross appearance lead to the suspicion that perhaps such associated infection accompanied all cases of fissure. To be sure, gross evidence was not present in all cases, but, on the basis of the previous study, it was not improbable that all such crypts would show microscopic evidence of infection. The possibility existed that residual infection in the crypts at least aggravated, if not originated, the anal fissure.

For these reasons, then, it was decided to prove or disprove this theory. The only way was to remove the crypts in the respective quadrant along with the fissure and associated abnormal tissue, follow these cases, observe the results, and compare them with cases treated by excision of the fissure alone. The technique is simple (see figure). The entire quadrant of the anal canal was excised in such a manner as to include the fissure, the crypts, the hemorrhoids, and associated abnormalities. Great care was exercised to avoid injury to muscle. The cut edge of mucosa was then anchored to the internal border of the external sphincter by continuous suture. A smooth wound, devoid of overhanging edges, which would heal easily, resulted. Approximately 300 patients were treated in this manner. They were followed for at least one year. None of the fissures to our knowledge has recurred. On the other hand, approximately 100 fissures were treated by ulcer excision only, usually as an office procedure. At least five are known to have recurred. The more thorough or adequate procedure is really very little more difficult to perform than the limited procedure. The superior results justify this effort.

COMMENT

Cryptitis is frequently observed in association with fissure, and it seems possible that such infection is the real cause of fissure. The probable sequence of events is cryptitis, burrowing of infection by way of the anal ducts or periductal lymphatics and following the path of least resistance underneath the loose skin distally. The comparatively thin skin, made friable by the effects of inflammation, would allow for its disruption just below the dentate line and eventually result in a fissure. Bowel movements would intensify the reaction; each acute attack would stimulate the formation of more indurated tissue. Each remission would allow the formation of fibrous tissue. This would account for the fibrous papillae and skin tags so frequently observed. The inability of the fissure or ulcer to heal spontaneously, because of a lack of drainage, would account for progression of disease in the formation of a subcutaneous sinus (fistula) somewhat beyond the fissure. From the viewpoint of pathogenesis, a fissure is a secondary opening of a fistula. The subcutaneous sinus seen in many cases of fissure would be another secondary opening. The analogy is definitely suggested. The layman's confusion in terminology of fissure and fistula may be scientifically justified.

The results in the 300 cases studied indicate that removal of infected crypts is important in obtaining a high incidence of cures. Removal of the corresponding crypts should be added to the classic operation for chronic anal fissure. This may be done safely without resulting scar formation at the anorectal ring. There is the possibility that anal fissure might behave, and should be treated, as an anal fistula. This phase of the subject requires more investigation.

SUMMARY AND CONCLUSIONS

This study presents a concept of the possible pathogenesis and treatment of chronic anal fissure. Failure to remove all pathological tissue, including infected anal crypts, may be a cause of recurrence.

TODAY'S MEDICINE IN UNDERDEVELOPED AREAS

John Z. Bowers, M.D., Salt Lake City

Recently there has been a growing interest in the economic plight of village people in distant lands. Bold new programs to increase food production, to provide opportunities for education, and to improve health have been launched with the support of the United States Government and private foundations. During the past year, I have spent about four months in India as medical advisor to the government of India and the Ford Foundation. The primary purpose of these visits was to assist in the development of a village health program that would integrate with the other aspects of the community development program in India.

The health of a villager in India is the result of the interplay of a number of factors, some of which would at first glance seem far removed from health. Any endeavor to improve the health of an Indian villager must consider existing health practices and prejudices, the role of indigenous medical practitioners, and related problems. The material in this paper attempts to emphasize some of these problems in the health field. Although the remarks refer to experiences in India, the basic problems apply to a number of countries that have predominantly peasant populations. The information and ideas have been gathered from travels to many village areas in India. I am particularly grateful to several outstanding Indian health leaders who have been willing to lead me through the maze of an Indian village or to tell me of the country and its problems. With the leadership of such persons as K. C. K. E. Rajah, D. S. Lakshmanan, and others, India is steadily moving forward in meeting her varied health problems.

FACTORS THAT CONTRIBUTE TO HEALTH

Size, Population Distribution, and Climate.—The size of a country, the distribution of its people, and its climate

---

Oscar Lewis, Ph.D., collaborated in this study.

Dean and Professor of Radiobiology, University of Utah College of Medicine, Salt Lake City.

Presented in the Scientific Assembly of the American Medical Association, June 1, 1953, New York.

are important factors in a nation's health. India is a vast subcontinent of 375 million people, 85% of whom live in villages. Facilities for transportation and communication are limited. Travel by air is easy between large urban centers, but the 500,000 villages have limited, if any, access to transportation, and for two to four months of the year monsoon rains isolate many of them completely. Thus, for really adequate medical care or preventive programs, the majority of the villages must be self-sufficient. A physician, a clinic, or a nurse 10 miles away often means no physician or nurse.

Education.—Health and education usually go hand in hand, and in India about 88% of the population is illiterate. Only about 25% of the villages have any facilities for primary education, and these are often overcrowded and poorly equipped. Several provinces have made two years of primary education mandatory. Frequently a school consists of a gathering, in a shaded place, of a teacher with a class of from 50 to 100 students varying in age from 6 to 16 years. There are 11 different languages and several hundred dialects. Obviously, these factors pose serious problems in any program of health education.

Religion.—Religious practices affect health in many ways. Dietary disciplines, such as the complete vegetarianism dictated by Hinduism, often swing the balance toward malnutrition or famine in lands where available protein foodstuffs are, at best, inadequate by modern standards. Attitudes toward animals may be of considerable health importance. India's 200 million cows are sacred. They often roam through markets, gardens, and homes devouring vegetation that is badly need for human consumption and they do not compensate for their food intake by returning a plentiful milk supply.

In areas populated by Moslems the segregation of women by the purdah system has resulted in a high incidence of tuberculosis. The caste system is unique to India, yet the attitude of segregation of the wealthy few from the impoverished masses reflects a problem in health work in any underdeveloped area. Actually, under the system of five major castes and numerous subcastes a physician or nurse of one caste group often could not treat a patient of another group. In the allocation of land areas, the low castes and the untouchables received land that was least promising for food production and wells or tanks that were most heavily contaminated or had the lowest reserve when supplies everywhere were low. The typical village of untouchables is a poor Indian village with inadequate huts, a foul well, and no usable latrines, and some of the natives are now faced with leaving even these because of the depredations of wild boars in their fields. The caste system has been outlawed, but, as with other attitudes involving segregation, many years will pass before it disappears.

Superstitions Regarding Disease.—All peoples, tribal, peasant, and urban, have their own beliefs and practices of health and disease, often based on many years of trial and error. These beliefs and practices are a most important factor in establishing programs to improve health. They are especially important in villages where religious practices are followed rigidly, and they are the basis for programs of health education, or health reeducation. Dr. Oscar Lewis, professor of anthropology at the University of Illinois, has been working with the Ford Foundation in India and has developed, by interview techniques, a large amount of valuable information regarding health attitudes in a north Indian village. It is impressive that these attitudes exist in a village within 15 miles of New Delhi, a modern, highly westernized city that has served as the seat of government for India since 1921 and has had a large Western population. For example, eight village adults of varying social status believe the following factors could cause typhoid, which is a very prevalent disease in village areas: (1) influence of bad spirits, (2) excessive heat in body, (3) working hard in the sun, (4) foul air entering the body, (5) upset stomach and constipation, and (6) eating watermelons of poor quality. It is evident that most of these ideas actually could be used in teaching the germ theory of disease. Similarly, the prevailing concepts of treatment or cure emphasize a low residue bland diet and interestingly, the desirability of using boiled water. Other methods of treating the disease were: (1) making offerings to the Goddess of the Neck; (2) use of browned flour, sugar, and milk; (3) use of milk or sugar, or only a small amount of milk; (4) no cold food, or no food; (5) use of boiled water from a new earthen pot; (6) use of a berry (*kondra*), cow urine, or water; and (7) tying one rupee in a cloth around the patient's neck. Since it is estimated that every adult in India has had typhoid, each of these persons has had personal experience with the disease, and a few had seen the members of their family immunized or had received some instruction from a health inspector or a nurse regarding treatment.

The main effort at health education in India has been directed at water-borne diseases, especially cholera. Many villagers realize that an unsafe water supply is related to diseases associated with diarrhea. They also prefer the natural taste of water from a tank even though it may be contaminated to that of adequately chlorinated water. Fuel supplies of coal or wood are so scarce and expensive that there is no facility for boiling water prior to consumption. Dried cow dung cakes are conserved to use as fuel for cooking. During the immediate premonsoon months, available village water supplies often reach such a low reserve that any water may be priceless and a villager will walk several miles each day to fill a small pot.

In contrast with the information on typhoid, which represents the best evidence of health education, following are data on smallpox, a disease from which 35,000 to 50,000 die each year. It is commonly believed that the following factors may cause smallpox: (1) evil spirit, (2) cold bath during a febrile illness driving heat inside the body that later comes out in blisters (especially if the stars are unfavorable), (3) heat accumulated in the body, and (4) disorder of the blood. Common methods of treatment and believed cures for smallpox are: (1) ashes applied to blisters, (2) bricks heated in a fire, with cow urine dropped on the bricks so that vapors will touch patient's body, (3) neem leaves hung at door to protect children from shadow of unclean persons, (4) vows to make an offering to village goddess for recovery, (5) the offering of songs of praise by women to the Goddess of Surgaon and praying for relief of patient, and

(6) five handfuls of grain left by the mother of the patient in a specified position at the outskirts of the village every day for five days.

Vaccination is not mandatory in all areas, and inadequate vital statistics, which are the responsibility of a village watchman, the *chowkadar*, allow many births to go unregistered. Mortality rates from smallpox range as high as 40%, although an effort is made to vaccinate every child before the age of 6 months and again at 6 years.

The ideas concerning the possible causes of smallpox that were given by the villagers indicate the greater ease with which basic ideas as to the transmission of waterborne disease may be understood, in contrast with diseases transmitted by respiratory routes or direct contact. The list of therapeutic measures emphasizes the role of the gods in curing disease. The indigenous medical practitioners emphasize this and place themselves as the intermediary between the gods and the patient. Cow urine is highly regarded because of the holy position of the cow. Devout persons may drink it for a purifying effect; it is used therapeutically in liver disease, and in typhoid it is used as a local compress.

NATIVE HEALTH PERSONNEL

India has only about 15,000 physicians for its 375 million people, but there are about 200,000 indigenous medical practitioners trained in the Ayurvedic or Unani systems of medicine. Since practically all of the medical care in rural India rests in the hands of these native practitioners, they are an essential force to be reckoned with in any program to bring public health and hygiene to Indian villages. The *vaid*, or *hakim*, receives four years of training in a program that includes anatomy, physiology, and pharmacy. Diseases are considered as conflicts between two or three humors, and diagnosis is based upon history and a physical examination that emphasizes inspection and careful palpation of the pulse. Ointments, brews, and pellets prepared from native herbs are often the basis of treatment. The native practitioners, however, are becoming increasingly acquainted with methods of Western medicine. Naturally, indigenous practitioners are on the defensive regarding their prestige in the village, and their methods of medical care are refined to insure their position as an intermediary for the gods, who, in cases of doubtful outcome, are responsible for any dire results. The native practitioner, be he a *vaid* of India or a *curanderos* of Central or South America, is a potent force who can assure success or failure in any program of medical progress. The naturopathic methods of these practitioners have a great appeal even to many literate members of their country.

In rural areas, midwifery still represents the only effort toward any program of maternal or child health. India's representative of midwifery, the illiterate hereditary *dais*, attends the delivery, often smears the cord with cow dung, and makes a few postpartum visits. She is unable to handle any complications of parturition. Her fee for a boy baby is usually two rupees (44 cents) and for a girl, one rupee (22 cents). Similar untrained midwives exist in other countries of Southeast Asia, and in the Philippines there is a group of Herculean men who are called in cases of labor complicated by contracted pelvis and, by dint of violent force applied to the abdominal wall, are expected to eject a living child. India's women, and to a lesser degree those of other countries in Southeastern Asia, are reluctant to accept medical care from men. Consequently the midwife is often the only existing means of medical communication with the family, and since, as in the United States of America, the wife rules supreme in the home, the midwife may be a key figure in determining the success or failure of health programs.

DISEASE PROBLEMS

In developing programs to raise living standards in underdeveloped areas, the first attack is on diseases that have the greatest importance in economic productivity. Any discussion of disease is limited, however, by the paucity of vital statistics. Malaria probably affects about 35% of the population, so that many Indians are malnourished, anemic, and feverish persons who are unable to perform a full day's work. Further, disease incidence rises sharply about one month after the monsoon season begins, a time when agricultural activity, especially rice growing, should be at its height. It has been estimated that the person with malaria loses about 10% of his potential income to the disease through purchase of nostrums and actual lost employment. Even when he is employed, however, his effectiveness is low.

In several provinces, vigorous programs of malaria control have resulted in a striking reduction in the incidence of the disease. Residual DDT spraying of dwellings every two months from July to November has been the sole measure that Dr. D. K. Viswanathan has used with success in Bombay province. In most areas this procedure alone will control malaria in one year. In particularly bad pockets, however, as many as three years will be required. A nationwide program for malaria control is now under development.

Statistics show that the incidence of intestinal helminthic disease, especially ancylostomiasis (hookworm disease), ranges as high as 90% in village areas. Actually the Indian villager has good habits of personal hygiene considering available resources. His major defect is a lack of understanding of what he may do to others. Bodily excreta are abhorrent to him. He rebels at the thought of visiting a latrine where others have deposited their feces. Indeed, it is necessary to use latrines in which previously deposited feces are invisible. Accordingly, the villager goes to the field and finds a fresh spot where he may deposit his feces, and, since practically all villagers go barefoot, ancylostomiasis is easily transmitted. Amebic and bacillary dysentery are prevalent in India and, as with malaria, are at their highest incidence in the monsoon season. Although there are no figures available regarding the economic impact of these disorders, ancylostomiasis and dysentery are the cause of a considerable reduction in the economic effectiveness of villagers in Southeast Asia.

Any program to increase food production should be geared to existing information regarding nutritional status. In southern India, the diet of villagers consists chiefly of rice. In central India, millet and rice are the major dietary constituents, and in northern India wheat is the primary foodstuff. It is interesting to note that the average height and weight are greatest in areas where the diet is representative of northern India. In the southern areas where rice is the chief component of the diet, many villagers refuse to eat eggs because of the possibility that they may contain an embryo. Fish serves as an additional protein source in some less devout areas, although the villagers will usually sell the fish to gain money rather than ingest it to gain much-needed calories. In West Bengal, efforts are being made to encourage stocking of fish in tanks and ponds and to encourage the cultivation of *dal*, a vegetable that has a high protein content.

Beriberi is not as prevalent as in the past, but undoubtedly many subclinical states of vitamin B deficiency exist. Probably the Indian custom of parboiling rice before it is milled produces a greater fixation of thiamin in the grain so that it is not easily absorbed by the body. Osteomalacia and rickets are frequently seen in northern India. It is said that osteomalacia was commoner when there was a larger Moslem population in India and purdah was practiced by them. Tuberculosis is prevalent, and it is estimated that about 500,000 persons die from this disease each year. A vigorous campaign of BCG vaccination is now being conducted by the government of India. India continues to be a great reservoir of tropical and exotic disease. There are probably one million persons in India that are suffering from leprosy, predominantly the tuberculid form of the disease with extensive nerve involvement and resultant crippling deformities. Despite expanding programs of vaccination, smallpox continues to be a significant disease, with a mortality rate as high as 40%. Foci of cholera lie dormant in many areas, to break with explosive violence at the time of religious festivals or other similar events when many thousands gather. Although antibiotics appear to reduce the number of vibriones in the stool, the clinical course of the disease is not appreciably altered, and glucose and saline given intravenously continued to be the prevailing methods of treatment. Information is badly needed on the epidemiology of cholera.

The continuing shortage of facilities, funds, and teaching personnel to expand medical education to a point where the actual needs for physicians are filled poses a serious problem at a time when programs for raising living standards place increased demands on personnel. Accordingly, programs have been established such as the cooperative venture between the government of India and the Ford Foundation to train persons who can serve as the health counterpart of the agricultural extension agent in the United States. The diversity and enormity of the village health problems in India suggest that it is most desirable to concentrate personnel on one or two key problems from which a breakthrough may occur. Disease associated with an unsafe water supply and inadequate sewage disposal probably have the greatest single economic impact, and accordingly these health extension workers will concentrate their energies on personal and environmental sanitation and hygiene. Again, in view of the enormity of the problem, the greatest returns should accrue from a program emphasizing prevention, with only enough activity in the curative field to excite and hold the villagers' interest. This, of course, primarily implies educational programs, and, in view of the strong cultural implications in the health field in countries such as India, a preliminary evaluation of existing health attitudes, the role of the indigenous practitioner or midwife, factionalism, and group conflicts are all questions that must be considered. In addition, existing health personnel who are working in the village programs will be given orientation courses that will be intended to alert them in regard to techniques of health education and the diverse problems that are implicit in working in a country such as India.

This is only one segment of the broad program that has been developed in India. New medical colleges have been established, and existing institutions have been strengthened. Schools for public health nurses are in operation, and the training of other paramedical personnel has been expanded. Primary and secondary health units for preventive and curative work are developing in several provinces. It is evident that the pangs of hunger and disease and the web of poverty go hand in hand. A nation cannot have economic health without physical health, and the interrelation of these two factors is of increasing importance in the world today.

CLINICAL NOTES

SUBACUTE BACTERIAL ENDOCARDITIS IN PENICILLIN-SENSITIVE PATIENT

C. A. Beck, M.D., Chicago

Chlorprophenpyridamine (Chlor-Trimeton) maleate and other antihistaminics have recently been used to decrease the percentage of all kinds of allergic reactions, including that to penicillin.[1] Because of this, we used chlorprophenpyridamine maleate in a patient with subacute bacterial endocarditis who had a severe sensitivity to penicillin, a rare combination and in addition an excellent test for the drug.

A penicillin-sensitive patient with a serious illness presents a dilemma in therapy. Only four courses are possible: (*a*) administration of penicillin regardless of risk, (*b*) attempted desensitization to penicillin, (*c*) use of other antibiotics with less likelihood of a successful outcome, or (*d*) administration of penicillin along with a substance such as an antihistamine or cortisone in an effort to obviate reactions. The following case history

---

From the Department of Medicine, Michael Reese Hospital.

The Chlor-Trimeton was supplied by the clinical research division of Schering Corporation through George Babcock Jr., M.D.

Dr. Albert Milzer and Miss Helen McLean, Department of Microbiology, and Drs. Jacob Schlichter, Jacob Meyer, and Paul Joseph, and Rachmael Levine, Department of Medicine, Michael Reese Hospital, assisted in this study.

of a patient with subacute bacterial endocarditis is illustrative of the failure of alternate *c*, and the success of alternate *d*. Desensitization was considered, but a recent experience of another physician whose patient suffered anaphylactic shock and death during this procedure militated against its use in this instance.

REPORT OF A CASE

The patient, a 49-year-old woman, was first admitted on March 18, 1952, with complaints of lassitude, weakness, malaise, and afternoon fever experienced since recovering from pneumonitis 10 weeks previously. Her history was suggestive of several attacks of rheumatic fever in childhood and adolescence. The history also revealed "heart disease" claimed since pregnancy 19 years previous to examination, intermittent ankle edema, and moderate dyspnea on exertion during the preceding several years. Blood pressure was 154/86 mm. Hg, pulse 92, respirations 16, temperature 101-103 F. There were crepitant rales in the posterior left lung field, cardiac enlargement to the anterior axillary line 5th costal interspace, grade 2 presystolic murmur at apex, grade 2 rough systolic murmur in aortic area, loud heart sounds, liver nontender and palpable 4 cm. below right costal margin, 2+ pitting edema of ankles, sedimentation rate 50, corrected 43, and electrocardiogram pattern essentially normal. The patient was placed on bed rest with a salt-free diet, and numerous diagnostic tests were performed. The antistreptolysin titer was 100-R-8. The result of the Weltmann serum test was 4. The temperature became normal, rales and edema disappeared, and the patient was discharged after four days. Because of this short course, however, the provisional diagnosis was transient bacteremia, rheumatic heart disease (inactive), and grade 2 cardiac decompensation. A blood culture, reported after discharge, showed Streptococcus faecalis, which was considered noncontributory in this case.

On May 13, 1952, after three weeks' therapy at home with chlortetracycline (aureomycin), 250 mg. four times a day, for a low grade fever, the patient was readmitted to the hospital. Physical findings were similar to those at the time of the first admission, but the systolic murmur was now grade 3 and the spleen firm, nontender, and palpable 1 cm. below left costal margin. Occasional extrasystoles were noted. A bigeminal rhythm, which began on May 14, changed to trigeminal on May 20 and reverted to normal on May 24. The second heart sound was then noted to be loud and slapping over the entire precordium. The sedimentation rates were 58, corrected 41, and 63, corrected 48. Blood cultures obtained prior to and after admission yielded an alpha prime Str. viridans. The diagnosis of subacute bacterial endocarditis could then be made. In vitro tests showed sensitivity to oxytetracycline (Terramycin), 0.0625 mcg. per cubic centimeter, to chlortetracycline, 0.0625 mcg. per cubic centimeter, and to penicillin, 0.005 Oxford units. The patient gave a history of a severe reaction including urticaria, pruritus, fever, and vesicular dermatitis of a month's duration following penicillin therapy 18 months previously. Skin tests with procaine penicillin, penicillin O, and Compenamine (l-ephenamine penicillin G) gave strongly positive results. In view of the positive skin tests and a history of reaction to penicillin, it was deemed advisable to institute therapy with other antibiotics. Oxytetracycline, 500 mg. every six hours, was given orally for nine days without appreciable change in the condition of the patient. In vitro studies then showed increased resistance of the organism to both oxytetracycline and chlortetracycline (0.5 mcg.). Chloramphenicol (Chloromycetin), 500 mg. every six hours, was administered from May 24 to June 23. The condition of the patient gradually improved, temperature became normal, blood culture became negative, and the patient was discharged in satisfactory condition. During therapy with chloramphenicol a moderate decrease in erythrocytes and hemoglobin was noted.

The patient was admitted for the third time on July 9, 1952. Physical findings were similar to those at the time of the previous admission except that clubbing of the fingers and petechiae of mucous membranes and of the hands were observed. Therapy consisted of three 10 cc. units of immune globulin on July 9, oxytetracycline orally, 500 mg. four times a day, and 500 mg. intravenously two times a day for 16 days from July 9 to July 25. Again the patient improved only to relapse when therapy was discontinued. Erythromycin became available on Aug. 20, and the patient received 500 mg. every six hours (orally) until Oct. 2. Studies showed that growth of organism was inhibited by 0.02 mcg. of erythromycin. The sedimentation rates were 48, corrected 44; 44, corrected 34; 53, corrected 32; 55, corrected 38; 56, corrected 40; 45, corrected 34; and 52, corrected 37. The blood culture became negative on Sept. 2 and remained so during the balance of the patient's hospital stay. The murmurs faded, temperature became normal, and it appeared the patient was cured. The patient had a slight cold for two days at the conclusion of therapy. She was discharged Oct. 8 with a normal temperature and was feeling well. Blood cultures were made at the time of discharge and again on Oct. 13. In each instance a Streptococcus with the same biochemical reactions as the organism originally isolated was obtained.

The patient was admitted for the fourth time on Oct. 18 with physical findings similar to those of previous admissions. Failure of four other antibiotics and the serious condition of the patient prompted us to employ penicillin in spite of the prior hypersensitivity reaction and the strongly positive skin tests to several types of this antibiotic. The reports of Simon and Sanger to the effect that combining an antihistamine with penicillin reduces the incidence of penicillin reactions prompted me to try administering chlorprophenpyridamine maleate injection, 100 mg. per cubic centimeter, in conjunction with the antibiotic. On Oct. 19, 10 mg. (0.1 cc.) of the antihistamine was given 30 minutes prior to injection of 600,000 units of procaine penicillin. Since no reaction was observed, the dose of penicillin was increased to 600,000 units two times a day on Oct. 20 (with 10 mg. of chlorprophenpyridamine maleate just before each injection). Penicillin dosage was further increased to 2 million units every six hours (with 5 mg. of chlorprophenpyridamine maleate in the same syringe) on Oct. 22. No reactions occurred. Therapy with carinamide, 1 gm. three times a day, was begun on Oct. 24. A mild pruritus and flat pink rash developed on Oct. 27. This was dissimilar to the patient's previous penicillin reaction and was readily controlled by Caladryl ointment (diphenhydramine in a calamine base). The dose of carinamide was decreased to 0.5 gm. three times a day, because of nausea. Penicillin dosage was reduced to one million units four times a day, with 10 mg. of the antihistamine in the same syringe. Treatment was continued in this fashion for 30 days. The sedimentation rates were 55, corrected 40; 50, corrected 38; and 46, corrected 38. The last sedimentation rate was taken two to four days before the patient was discharged. The blood culture became negative early in the course of therapy and has remained negative on repeated examination up to the time of this report (June, 1953). The condition of the patient improved rapidly, and she was discharged as cured.

SUMMARY AND CONCLUSIONS

There are two ways to study the value of a drug. One is the statistical approach, with large groups in the general population. The other method is its use in severe cases, which brings out the limits of usefulness. A patient with subacute bacterial endocarditis, sensitive to various penicillin preparations, was successfully treated without reaction by a combination of penicillin, one million units, and chlorprophenpyridamine (Chlor-Trimeton) maleate, 10 mg. per injection. This result is significant since other antibiotics, to which the patient was not sensitive, failed to achieve the desired clinical response and because of the severity of the previous penicillin reaction.

FATAL APLASTIC ANEMIA FOLLOWING QUINACRINE THERAPY IN CHRONIC DISCOID LUPUS ERYTHEMATOSUS

Leo G. Parmer, M.D., Ph.D.
and
Arthur Sawitsky, M.D., New York

The use of quinacrine (Atabrine) has declined considerably since the introduction of newer antimalarials. However, recent new indications for the drug have revived its use. Page[1] reported on the treatment in 18 cases of chronic discoid lupus erythematosus with quinacrine with striking results. Only one patient failed to improve considerably, and in a few cases all the lesions completely disappeared within six weeks of the start of treatment. In two patients associated changes of rheumatoid arthritis disappeared as the skin condition improved. This latter finding was extended by Freedman and Bach,[2] who treated 23 arthritic patients with quinacrine, of whom all but one were said to have improved. Pain subsided, soft tissue swelling decreased, and movement became free and more vigorous. Six to 10 weeks of therapy were necessary before all signs of joint inflammation disappeared. In this series only one side-reaction, a macular eruption, developed in a patient who had received 0.8 gm. daily for four days.

The successful results in rheumatoid arthritis were repeated in a series reported from Norway.[3] Eleven patients with the disease were treated for from six weeks to five months. All of the patients noted a decrease in their pain, and in five of the patients objective signs of improvement were noted. As an incidental finding, two patients with bronchial asthma who had been admitted repeatedly to the hospital in status asthmaticus were treated for six months with quinacrine with freedom from symptoms and signs of asthma.

In this country, the promising results of quinacrine in discoid lupus erythematosus were confirmed in a series of 30 patients by Sawicky and associates.[4] In 21 cases there was prompt and definite improvement despite the fact that the patients had received intensive therapy previously with other medicaments with varying results. In six cases the condition was reported as having cleared completely, and only three patients failed to respond satisfactorily or relapsed during therapy or soon after its cessation. Similar results by Cramer and Lewis [5] with six patients and Wells [6] with six patients have been reported. These favorable results in the treatment of discoid lupus, and subsequently the favorable response in both rheumatoid arthritis and bronchial asthma, make it likely that the drug will again be used more extensively. The following report deals with a patient in whom fatal aplastic anemia developed after she received quinacrine for the treatment of chronic discoid lupus erythematosus.

REPORT OF A CASE

The patient was a 36-year-old Negro woman, a teacher, who was admitted to the skin and cancer unit of the New York University Hospital on July 25, 1950, with a complaint of a rash over the cheeks of five or six months' duration. A tentative diagnosis of discoid lupus erythematosus was made, and the patient was treated with 2% sulfur ointment and vitamin B complex. Several months later, the patient returned to the clinic without improvement and 3% Vioform cream (5-chloro-7-iodo-8-hydroxyquinoline) was prescribed. On July 24, 1952, the patient again returned, complaining of a recurrence of the lesion and the appearance of new ones on the upper eyelids. The lesions were described as oval and very scaly, with a red papular base. A punch biopsy specimen was taken at that time and a report was made as follows: "There is a dense cellular reaction in the upper cutis. The reaction is also periadnexal; interspersed among the cells are deposits of pigment which, for the most part, seem to be intracellular. The cells are almost entirely small round cells. The overlying epidermis is thinned and flattened. There is a liquefaction necrosis of the basal cell layer. Hyper-granulosis and hyper-keratosis are present. The Van Wiegert stain was not diagnostic." The diagnosis was discoid lupus erythematosus.

On Aug. 27, 1952, oral administration of 1 gm. of quinacrine was started twice a day. Two weeks later the skin lesions appeared to be better, but five weeks after the beginning of quinacrine therapy the patient began to complain of a general "achiness," which disappeared the next week. However, at the time the patient said that she "felt better," the sedimentation rate was 22 mm. per hour, and the blood count revealed a hemoglobin level of 13 gm. per 100 cc., a red blood cell count of 4,600,000 per cubic millimeter and a white blood cell count of 3,800, with 65% polymorphonuclears and 38% lymphocytes. Quinacrine therapy was continued.

Eight weeks after therapy was started, the lesions appeared less raised and less active and vitamin B_{12} injections were instituted. After 10 weeks of therapy the lesions were described as being red, and parenteral vitamin B_{12} therapy was continued. After this visit the patient did not return to the clinic.

Four months after institution of quinacrine therapy, the patient was admitted to Queens General Hospital with complaints of bleeding. Three weeks prior to admission, she noted the onset of an upper respiratory infection with a cough productive of whitish material and occasionally streaked with blood. Two weeks prior to admission she developed chills and fever to 103 F. Her physician said she had "jaundice and pneumonia," and treated her with penicillin and chlortetracycline (aureomycin). The temperature continued to spike to 105 F for a week, and five days prior to admission she noted the onset of vaginal bleeding despite the fact that she had had no menses since a spontaneous menopause two years previously. On the morning of admission the patient collapsed at home and was subsequently hospitalized. Her past history revealed that she had an attack of rheumatic fever in 1937 associated with joint pains. She had a tonsillectomy following that episode. She had occasional slight exertional dyspnea but no ankle edema or orthopnea. The patient denied venereal disease. She did not smoke or drink.

Physical Examination.—On admission the temperature was 101.6 F, the pulse 112, the respiration rate 20, and the blood pressure 110/78 mm. Hg. The patient was well nourished, well developed, and in no acute distress. Over both zygomatic arches and both upper lids, there was a scaly, darkly pigmented macular eruption. There was questionable icterus of the scleras; the pupils reacted to light and accommodation, and the conjunctivas were pale. There were numerous purpuric areas over the palate, pharynx, and tongue. The neck was supple, and the trachea was in the midline. The thyroid gland

[6] Wells, G. C.: Treatment of Chronic Discoid Lupus Erythematosus with Atabrine, J. Invest. Dermat. **19**: 405-407 (Dec.) 1952.

was not palpable. There were a few small cervical nodes papable with no other enlargement. The heart was not enlarged, the rhythm was regular, and there was a grade 1 systolic murmur at the apex. The lungs were clear to percussion and auscultation. The abdomen revealed marked tenderness in the right upper quadrant; the liver, kidney, and spleen were not palpable. The reflexes were hyperactive but bilaterally equal. No pathological reflexes were elicited. Pelvic examination revealed blood at the vaginal orifice; the cervix was smooth and the adnexae were not palpable. Blood was found on the glove after rectal examination.

Laboratory Data.—Results of blood studies on admission were as follows: The hemoglobin level was 8 gm. per 100 cc. and the red blood cell count 2 million per cubic millimeter. The white blood cell count was 1,400, with 15% polymorphonuclears and 85% lymphocytes. The hematocrit value was 25, with reticulocytes 2%, and there were less than 20,000 platelets. The bleeding time was 60 minutes and the coagulation time 40 minutes, with no clot retraction for three days. The corrected erythrocyte sedimentation rate was 52 mm. per hour (Wintrobe), and the prothrombin time 82% of normal. Other laboratory data were negative results of direct and indirect Coombs' tests, a blood sugar level of 107 mg. per 100 cc., a urea nitrogen level of 13 mg. per 100 cc., an alkaline phosphatase level of 3.1 units, and an icterus index of 5. There was no cephalin flocculation, and the total protein level was 7.2 gm. per 100 cc., with 3.8 gm. of albumin and 3.4 gm. of globulin. Three successive L.E. cell preparations were negative. Results of other blood studies are shown in table 1. The urine contained albumin (2+) and was grossly bloody.

Table 2 shows the results of bone marrow counts. No megakaryocytes or platelets were seen on either smear. Marked hypoplasia of all elements with a relative lymphocytosis was noted. Rouleaux formation was marked in the iliac marrow. There was no evidence of leukemia on either smear. Mast cells were seen in all preparations. This finding lends support to the diagnosis of a secondary aplastic anemia.[7]

Hospital Course.—The patient's temperature continued to be elevated for the first five days after admission, but it returned to normal with antibiotic therapy. Vitamin K, 100 mg. of corticotropin daily, and repeated blood transfusions were given. Despite therapy, the patient continued to bleed from the mouth and genitourinary tract. The sputum remained blood streaked. On the eighth day of hospitalization the patient suddenly became aphasic and incontinent, and sank into a semistuporous state. There was left-sided weakness with bilateral Hoffman signs and nuchal rigidity; no Babinski sign was elicited. A diagnosis of subarachnoid hemorrhage was made. The temperature rose to 106.6 F. Bleeding from all orifices increased and, despite transfusion of 500 cc. of fresh blood, the patient died. Permission for autopsy was not granted.

COMMENT

There have been several reports dealing with the development of aplastic anemia due to quinacrine therapy in armed forces personnel in the Southwest Pacific. These were summarized by Custer, who reported a total of 57 fatal cases.[8] Only two other cases have been found in which fatal aplastic anemia occurred after quinacrine therapy. One of these was in an African native [9] and the other in a Costa Rican.[10] The former report merely stated that the disease developed after administration of therapeutic doses of quinacrine; in the latter case it occurred after a prolonged suppressive regimen.

One of the questions that has arisen is why no cases of aplastic anemia occurred among troops taking quinacrine in areas other than the Southwest Pacific. Custer explains this on the basis that 0.1 gm. of quinacrine was given six or seven times a week continuously in the malarial area of the Southwest Pacific as compared to 0.1 gm. three times a week only during the hot months in other areas, such as the Mediterranean. Furthermore, strict adherence to the quinacrine regimen was not complete in the latter area.

It may be significant that about 50% of the Army cases of aplastic anemia occurred in patients who had the quinacrine dermatitis complex prior to the development of the blood dyscrasia. In our case, a chronic skin disease, although of a different type, was present. Patients with chronic discoid lupus may be unusually sensitive to drugs that suppress the bone marrow function. Robinson and associates [11] described leukopenia as a complication of chloramphenicol therapy of discoid lupus.

The mechanism of quinacrine aplastic anemia was investigated by one of us,[12] when it was found that the drug entered the bone marrow in high concentration. However, most of the drug was found in the granulocytic rather than the red cell series. This obviously would not substantiate a direct toxic effect of quinacrine on all the elements of the marrow such as occurs in benzol poisoning. Furthermore, quinacrine also concentrated in lymphocytes, and these are not affected in aplastic anemia. One of us (L. P.) concluded that there was no correlation between the concentration of quinacrine in the various blood cells and the cells affected in aplastic anemia. Because of this finding and because of the low incidence of aplastic anemia among the millions of service men who had taken the drug, it was presumed that the dyscrasia was a result of an idiosyncrasy to the drug.

SUMMARY

A case of aplastic anemia occurring after ingestion of quinacrine (Atabrine) is described. It is the first such case to be reported as occurring in the United States and followed treatment for chronic discoid lupus erythematosus. There is evidence that such a toxic response may be greater in patients with certain chronic skin diseases than in the general population. As a precaution, repeated blood cell counts should be done to determine if further administration of the drug is dangerous.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

Absorbable Gelatin Film.—Gelfilm (Upjohn).—A sterile, nonantigenic, absorbable, water-insoluble, gelatin film.—Absorbable gelatin film is obtained by drying on plates at constant temperature and humidity a specially prepared gelatin-formaldehyde solution. It is subsequently sterilized by dry heat at 146-149° for 12 hours.

Actions and Uses.—Absorbable gelatin film is used as an aid in the surgical closure and repair of defects in such membranes as the dura mater and the pleura. It is nonporous and has no hemostatic action. In the dry state absorbable gelatin film has the appearance and stiffness of cellophane of equivalent thickness, but when moistened, assumes a rubbery consistency and can be fitted to rounded, irregular surfaces. Its rate of absorption after implantation ranges from one to six months, depending upon the size of the film employed and the tissue in which it is implanted. Dural implants are less rapidly absorbed than muscle implants. When it is employed as a dural substitute, at least 70 days are required for absorption. This allows sufficient time for healing of the arachnoid layer and formation of new dura, which requires only a few weeks. It also helps to prevent the development of adhesions between the regenerating dura and the arachnoid. Absorbable gelatin film is nonantigenic and does not produce undue inflammatory reaction or other undesirable sequelae.

Dosage.—Absorbable gelatin film, which is approximately 0.075 mm. thick, is applied in the form of sheets. Prior to use the film is soaked in isotonic sodium chloride solution and then cut to the desired shape. For covering dural defects it is applied to the surface of the brain; the edges are tucked beneath the dura, and the wound is closed in the usual manner. The moist film may be sutured loosely to the dura, but this must be done carefully to avoid tearing the material. For covering pleural defects a similar technique is followed, except that it is preferable to anchor the film in place by means of small interrupted silk sutures.

Absorbable gelatin film may be stored indefinitely. To avoid contamination, sterile packages should not be opened until the contents are ready to be applied. When necessary, the film can be resterilized at 140° C for four hours.

Tests and Standards.—

Physical Properties: Absorbable gelatin film is a light yellow, transparent, brittle sheet 0.076-0.228 mm. thick, with a very slight, bouillon-like odor and taste. It is practically insoluble in acetic acid and water. It assumes a rubbery consistency after being in water for a few minutes.

Identity Tests: Transfer to a 250 ml. beaker about 1 gm. of absorbable gelatin film, add 100 ml. of water, boil for 5 min., and filter while hot. To 1 ml. of cool filtrate add 1 ml. of trinitrophenol T.S.: a turbidity is produced. To another 1 ml. portion of the cool filtrate add 1 ml. of tannic acid T.S.: a turbidity is produced.

Purity Tests: Char about 1 gm. of absorbable gelatin film, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 1.0%.

Assay: (Digestibility) Place about a 50 mg. piece of absorbable gelatin film in water until it becomes rubbery, lift from the water, and remove excess water between pieces of filter paper. Place the wetted sample in a 150 ml. glass-stoppered Erlenmeyer flask which contains 100 ml. of a 1% solution of pepsin-N.F. in 0.1 *N* hydrochloric acid previously warmed to 37°. Maintain at 37°, and agitate gently and continuously until digestion is complete. The average digestion time is not less than 4 hours.

The Upjohn Company, Kalamazoo, Mich.

Gelfilm: Box of six absorbable gelatin films in individual sterile envelopes; single films are approximately 100 mm. by 125 mm. by 0.16 mm. U. S. trademark 561,532.

Antihemophilic Plasma (Human).—Irradiated antihemophilic plasma (human) is the sterile plasma prepared in a manner to prevent destruction of the relatively labile active fraction by pooling plasma obtained by centrifuging whole blood from approximately 20 donors. After sterilization by ultraviolet irradiation, the product is dried from a frozen state under high vacuum. The product meets the requirements of the National Institutes of Health of the United States Public Health Service.

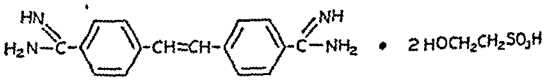
Actions and Uses.—Antihemophilic plasma (human) is human plasma processed so as to prevent denaturation of the antihemophilic globulin component present in freshly prepared plasma. It is administered for the temporary reduction of the dysfunction of the hemostatic mechanism in hemophilia.

Dosage.—Antihemophilic plasma (human) is administered intravenously. It is employed as a solution, prepared by restoration of a freeze-dried preparation equivalent to either 60 o 120 cc. of citrated liquid plasma with either 25 to 50 or 5 to 100 cc. of water for injection, depending on the volume t be used. Each 60 cc. equivalent of citrated liquid plasma, whic is equivalent to 50 cc. of original plasma or 100 cc. of circulating whole blood, will maintain a normal clotting time fo several hours to two days. This dose is usually sufficient fo children; twice this amount may be required for adults. Th maintenance dosage is dependent upon the weight and respons of the patient. Injections should be repeated so as to maintain normal clotting time; repeated doses do not lose their effectiveness.

Hyland Laboratories, Los Angeles.

Dried Antihemophilic Plasma (Human): 50 cc. and 100 cc. bottles of plasma plus anticoagulant dried from the frozen state, packaged with 50 cc. and 100 cc. of 0.1% citric acid diluent, respectively.

Stilbamidine Isethionate.—$C_{16}H_{16}N_4.C_4H_{12}O_8S_2$.—M. W. 516.59. —4,4′-Stilbenedicarboxamidine di (β-hydroxyethanesulfonate).—The structural formula of *stilbamidine isethionate may be represented as follows:*



Actions and Uses.—Stilbamidine isethionate, a water-soluble salt of an aromatic diamidine base, exhibits chemotherapeutic properties useful in the treatment of certain serious protozoan and systemic fungal infections. Although stilbamidine, like certain other diamidines, also inhibits other types of microorganisms as well as tumor cells, its use in the treatment of other infections or in neoplastic diseases has not been established. Until more conclusive evidence becomes available, use of the drug should be restricted to the treatment of early African trypanosomiasis (except in cases with significant spinal fluid changes) and kala-azar (except in mild leishmanial infections responsive to pentavalent antimony), especially when antimony therapy is contraindicated because of intercurrent tuberculosis, systemic actinomycosis, and generalized North American blastomycosis. It is not effective in the treatment of Torula infections.

Stilbamidine isethionate is detectable in the blood and urine in relatively high concentrations within a few minutes after either oral administration or parenteral injection of a single maximum tolerated dose. The blood level falls rapidly within 30 minutes, despite differences in the maximum dose tolerated by various routes. A rapid fall in urinary excretion occurs after the first two hours. With daily administration, the amount eliminated tends to remain unchanged regardless of the dosage. Its rapid disappearance from the blood is only partially attributed to urinary excretion. The unusual adsorptive effects of the drug on proteins of the serum, plasma, and other body fluids is believed to account for its rapid disappearance from the blood. Current methods for its detection are not sufficiently accurate to permit definite conclusions concerning its metabolic fate in the body. The amounts fixed in the tissue proteins or viscera have not been determined. Penetration of the meningeal barrier by the drug is poor. Intrathecal administration is not feasible because of its local irritant effect, and intramuscular injection produces local inflammation and pain at the site of administration. Concentrated solutions administered intravenously may produce thrombophlebitis.

During or immediately following intravenous injection, many or all of the following symptoms and reactions have been elicited or observed, approximately in the order of decreasing incidence: fall in blood pressure, rapid, thin pulse, facial flushing, dizziness, salivation, sweating, headache, nausea, vomiting, dyspnea, formication, syncope, lethargy, fecal and urinary incontinence, and edema of the eyelids and face. These side-reactions are usually transitory and disappear within 10 to 30 minutes. They are less severe with intramuscular injection and slow intravenous drip. In kala-azar, a modified Herxheimer reaction may occur within six hours following the first injection. The occurrence of a unique neuropathic syndrome involving progressive sensory changes in the distribution of the trigeminal nerve is a late toxic manifestation attributed to stilbamidine. Two to five months after a course of therapy, patients may gradually observe paresthesia, anesthesia, hypalgesia, and numbness (usually confined to the face). Sensibility to light touch is decreased, but usually pain, temperature, and pressure sense remain intact. The same findings may apply to the neck and waist. The incidence of occurrence of these late neuropathic effects is considered to be above 50%. The symptoms often disappear slowly, but they may persist indefinitely. The neurotoxic effects of the drug have been sufficiently troublesome to influence physicians against using it for treatment of trypanosomiasis and leishmaniasis.

Freshly prepared solutions of the drug administered in therapeutic doses have not been associated with hepatic or renal injuries, which formerly occurred following the use of ready-made solutions exposed to ultraviolet light. However, both hepatic and renal function should be determined prior to therapy as stilbamidine is contraindicated in hepatic or renal dysfunction. Partial deterioration of the drug is produced by the action of ultraviolet light on the unsaturated stilbene linkage. Solutions exposed to heat or light contain toxic deterioration products, but such deterioration does not occur when the drug is stored in dry form away from heat and light. Freshly prepared solutions should be similarly protected. Following injection, patients should be warned against excessive exposure to sunlight on the premise that stilbamidine remaining in the skin may be altered and the toxic products thus formed may initiate selective nerve injury.

Dosage.—Stilbamidine isethionate is administered intravenously by continuous, slow drip. A freshly prepared solution of the dose to be used, dissolved in about 200 cc. of either 5% dextrose in water for injection or isotonic sodium chloride solution, is infused over a period of two hours. Slow infusion is essential to avoid a fall in blood pressure. The solution should be protected from light by covering the container with black paper or a heavy towel.

The suggested average adult dose is 150 mg., repeated every 24 to 48 hours for a course of about 15 injections. It is advisable to initiate therapy with a 50 mg. dose, increasing this to 100 mg. for the second dose, and to 150 mg. for the third dose. It is suggested that the patient be placed on a low protein, low purine-type diet, which is thought to avoid certain antidimidine effects of proteins high in arginine. The dosage and frequency of administration of the drug should be altered when necessary to meet the requirements of the individual patient. The physician should become familiar with the reactions and side-effects expected from the use of stilbamidine.

Tests and Standards.—

Physical Properties: Stilbamidine isethionate is a white, odorless, crystalline powder that slowly darkens on heating above 250° and melts with decomposition at 325-335°. It is freely soluble in water and practically insoluble in ether. The amount which dissolves in alcohol to form 100 ml. of solution is about 0.3 gm. Stilbamidine isethionate is stable in air, but is decomposed by light. The pH of a 1% solution is 5.0-7.0.

Identity Tests: Dissolve about 50 mg. of stilbamidine isethionate in 2 ml. of water in a test tube, incline the tube, and slowly add 1 ml. of sulfuric acid down the wall: a white precipitate forms and a light yellow ring forms at the junction of the liquids.

Dissolve about 50 mg. of stilbamidine isethionate in 20 ml. of water: the solution exhibits an intense blue fluorescence under ultraviolet light.

Dissolve about 50 mg. of stilbamidine isethionate in 10 ml. of water. Make the solution alkaline with ammonia T.S. Filter the white precipitate which forms, wash with water, and dry at 105°: the product melts with decomposition at 270-280°.

A 0.0005% solution, prepared as described in the spectrophotometric assay for stilbamidine isethionate, exhibits an ultraviolet absorption maximum at about 328 mμ [specific absorbancy, E(1%,1 cm.), about 866] and a minimum at about 258 mμ, with an inflection point at about 225 mμ.

Purity Tests: Dry about 1 gm. of stilbamidine isethionate, accurately weighed, at 105° for four hours: the loss in weight does not exceed 1%.

Char about 1 gm. of stilbamidine isethionate, accurately weighed, cool the residue, add 1 ml. of sulfuric acid, heat cautiously until the evolution of sulfur trioxide ceases, ignite, cool, and weigh: the residue does not exceed 0.1%. Reserve the residue for the heavy metals determination.

Dissolve the residue from the ash determination by heating in 2 ml. of diluted acetic acid and by washing the dish thoroughly with 10 ml. of hot water. Cool the combined solution and washings, and run a *U.S.P. heavy metals test:* the amount of heavy metals does not exceed 10 ppm.

Assay: (Stilbamidine Isethionate) Prepare a 0.0005% solution of stilbamidine isethionate as follows. Transfer to a 100 ml. low actinic volumetric flask 0.1 gm. of dry stilbamidine isethionate, accurately weighed, fill to the mark with water, and mix. Transfer to a second 100 ml. low actinic volumetric flask 5 ml. of this solution, fill to the mark with water, and mix. Transfer to a third 100 ml. low actinic volumetric flask 10 ml. of this last solution, fill to the mark with water, and mix. Spectrophotometrically determine the absorbancy in a 1 cm. quartz cell at 328 mμ, using water as a blank. The concentration of stilbamidine isethionate in the solution in mg./ml. ≃ absorbancy ÷ 86.6. The amount of stilbamidine isethionate is not less than 95.0 nor more than 105.0%.

Dosage Forms of Stilbamidine Isethionate

POWDER. The powder responds to the identity tests and assay for the active ingredient in the monograph for stilbamidine isethionate.

EXCESSIVE VITAMIN A AND CONGENITAL ABNORMALITIES

Experimental studies have shown that a lack of vitamin A in the maternal diet during gestation results in widespread structural abnormalities in the young. Pregnant rats maintained on a vitamin A-deficient regimen have been reported to have fewer live young and an increased incidence of fetal reabsorption. Their young show an increased proportion of congenital defects in the visual, cardiovascular, or genitourinary systems.[1] Contrarywise, it has recently been found [2] that excessive intake of vitamin A also caused congenital defects to appear in offspring of mothers that received this supplement. One hundred fifty female rats were studied after being mated. One hundred received orally 35,000 I.U. of vitamin A per day from the 2nd, 3rd, or 4th to 16th day post coitus, while the 50 control animals received no extra vitamin. All animals were killed at, or near, term and the young examined for gross congenital defects.

In the control group, 44 of the 50 rats produced litters with a total of 410 apparently normal young being formed. Thus, 88% of the animals of the control group had successful pregnancies. On the other hand, of the 100 rats mated that received excess amounts of vitamin A, only 10 carried young to the end of the study (10% successful pregnancies). Thus, 58% of the animals whose mothers received excessive amounts of vitamin A showed congenital defects, while no congenital defects were observed in the control group. Cranial deformities were found constantly in the young of the test group. In this deformity there was an extrusion of the brain to the external surfaces of the head, with a membranous film covering the exposed brain surface. In addition to the skull deformity, other congenital defects were also noted sporadically, such as harelip, cleft palate, and defects in eye development.

These studies indicate that ingestion of excessive amounts of vitamin A by pregnant animals as well as severe restriction of this dietary factor produces severely deliterious developmental effects, an observation which suggests that there is an optimal range of vitamin A dosage just as there is for other dietary essentials.

BRUCELLOSIS

In the last two years notable advances have been made in our knowledge of brucellosis, and this has been presented in a technical report from the World Health Organization.[1] Infection with Brucella abortus may remain inapparent or subclinical or it may become manifest a an acute febrile disease of limited duration or a long continued disease with periodic exacerbations. A positive culture is the only sure criterion of the presence of the disease. This may be from the blood, bone marrow, a recently enlarged lymph node, the cerebrospinal fluid urine, or discharge from an abscess. Other diagnostic aids are (1) the sero-agglutination test, which when carried out with a suitable antigen and satisfactory technique almost always gives a significant positive result in the presence of active infection (positive reactions of low titer should be rechecked); (2) the complement-fixation test, which, although used by some, is believed by the Expert Committee to have no practical value; (3) the opsonocytophagic test, which the committee also regards as unsuitable for diagnostic use despite the fact that it has its adherents; (4) the intradermal test, which when positive unfortunately denotes only that the patient has had previous contact with Br. abortus but does not indicate active infection; and (5) a normal leukocyte count or leukopenia with or without a relative lymphocytosis in a febrile patient, which while not pathognomonic is nevertheless suggestive of brucellosis and should lead to the taking of cultures.

Of all the possible sources of culture material Spink and his co-workers [2] believe that sternal marrow yields the greatest percentage of positive results. The special culture mediums now available are considered superior to guinea pig inoculation. These authors find the agglutination test of special value in patients who have been empirically treated with antibiotics with the result that cultures are negative, but they warn that there is a wide variation in the reliability of antigens and that false positive results may occur as a result of cross agglutination in patients with tularemia or patients who have been immunized against cholera.

Elsewhere in this issue Spink and Thompson (page 1162) report two cases of human infection with Br.

abortus strain 19, a relatively innocuous strain used for vaccinating cattle. Both patients were veterinarians engaged in giving vaccinations. The authors present the first definitive proof that human infections can occur as a result of invasion by strain 19, although one previously reported case in a veterinarian was probably from this source. They therefore issue a warning to veterinarians that strain 19 vaccine contains a viable pathogen and that it should be handled only by qualified persons, preferably veterinarians, and with the knowledge that accidental contact with it may result in active brucellosis.

DRAMA IN STATISTICS

When persons speak of the dryness of statistics they are, of course, generally expressing their boredom rather than voicing the conclusion from a well-considered appraisal. In reality, the amount of human success, suffering, failure, and happiness that is packed into some statistical reports is, in the literal sense of the word, tremendous: It should make one tremble.

A convenient example is no. 10 of volume 37 of the Special Reports from the National Office of Vital Statistics, dated September 11, 1953. It begins with the sentence, "In 1950, there were 1,452,454 deaths registered in the United States . . . excluding the armed forces overseas." If every death is thought of as the final defeat of some individual struggling for existence, as the ultimate frustration of teams of physicians and nurses, and as a crisis in the adjustment of surviving families and close friends, the number 1,452,454 takes on an impressive significance that staggers the imagination. And consider what that phrase, "excluding the armed forces overseas," means to fathers, mothers, and wives!

The report continues, "The death rates for most states in 1950 were the lowest on record, continuing the downward trend that has characterized mortality rates since 1900." This sentence must fill the heart of every research worker with hope akin to fear. For how much of this progress, which seems too wonderful to be true, should we credit Domagk, the protagonist of sulfonamides, Fleming, the pioneer in antibiotics, and the many other earnest toilers in medical research laboratories? But especially, one asks himself, how long can this rate of progress be kept up? Will it all be undone by some gigantic folly of mankind, such as another suicidal war?

The statistics show that the states of the Union vary widely in their death rates. "The highest death rates recorded for the residents of any state in 1950 were 11.4 per 1,000 population for New Hampshire and 11.1 for Missouri; the lowest were 7.2 for Utah and 7.7 for North Carolina." The difference between 11.4 and 7.2 is striking even to a nonmathematician; translated into terms of human life it means that whoever discovers the reason for this difference between Utah and New Hampshire will make a contribution to preventive medicine. Part of the explanation of the difference to be sure, lies in a remarkable map on page 248 of the report. It shows that the population of New Hampshire is elderly compared with the youthful population of Utah. The segregation of old from young in the United States is one of the peculiar consequences of the denial of work opportunities after a fixed retirement age.

Another peculiar consequence is seen in the relative frequency of chronic disease, which especially involves older persons. Other important factors must complicate this problem, however. Malignant neoplasms are more frequent in some states than in others, with a ratio of 18 to 7 between the highest and lowest. Cardiovascular disease in some states exceeds that in some others, with a ratio of 67 to 24. There are other factors besides age, and whoever succeeds in identifying them will do humanity an immense service.

Accidents, according to the report, are one of the leading causes of death. Death rates for motor-vehicle accidents ranged from 11.2 per 100,000 population for residents of Rhode Island to 50.6 for Nevada. The total of motor-vehicle accident deaths for the U. S. in 1950 was 34,763. No Carthaginian or Aztec idol ever demanded the death and mutilation of so many human sacrifices as does that demon, the collective driver of the American automobile. Psychiatrists should consider the advisability of personifying this evil genius of our day, giving him a name, picturing him with fangs and claws, and setting up images of him to serve as hate-objects. No images, however horrible, could outdo the stark statistical reality.

The tendency to segregate old from young was noted above; it is strikingly shown in the map and tables of this report. In one state the median age of the population is 23.6 years; in another it is actually 33.7. If smaller geographic units are compared, even more striking disparities can be discovered. Recently two suburbanites working in Chicago compared the death rates of their communities; one was nearly three times the other. The one contained several large homes for old persons; the other was a one-class suburb filled with successful young couples with children in school. Moreover, it was evident that, when the children finished school, many of the families moved back into city apartments. Said one of the suburbanites, whimsically paraphrasing a famous remark of General MacArthur's, "We of Winnetka never die; we only move away."

Thus statistics even mark the passing of the old family homestead. Aging parents no longer greet a returning son with the words "You're as welcome as the flowers in May" as they show him to the bedroom he had in his boyhood. There is no spare bedroom, and he has to sleep with his feet in the entrance-hall and his head in the kitchenette. Stastistics are not dry; all this comedy and tragedy is there, implicit in the numbers. The numbers are necessary, and the diligent statistician deserves our gratitude.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

In traveling about the country these past few months I have found evidence of a great lack of knowledge of medical economic affairs within the profession. This situation must be corrected if we are to carry on the fine traditions of medicine. And, because I believe it is essential that every physician have a knowledge of the problems faced by officers of the American Medical Association and its House of Delegates, I try to bring you each month some message that is pertinent and of compelling interest to the medical profession.

The subject of this page, for example, should be of utmost concern to every doctor in the nation. It deals with the provision of medical care for military dependents. Last April the Secretary of Defense appointed the Citizens Advisory Commission on Medical Care of Dependents of Military Personnel. Its chairman was Harold G. Moulton. The commission was instructed to study the problem and return with a report in June. Despite the great complexities of such a broad subject, an investigation of sorts was completed within the allotted time and a report was made.

The commission had posed for itself a series of 12 questions. These were: (*a*) Should dependents be provided medical care as a matter of right? (*b*) What are the advantages of having dependent care provided by the military establishment? (*c*) Would morale requirements be met simply by an increase in pay? (*d*) How does the present system operate? (*e*) What is the source of disagreement between civilian medical agencies and the military services? (*f*) Should the care program be extended to all eligible dependents? (*g*) How should dependent medical care be financed? (*h*) What safeguards are necessary? (*i*) What types of illnesses should be included? (*j*) What military personnel should be eligible? (*k*) What types of dependents should be eligible? (*l*) What changes in budgetary procedure are necessary?

The commission concluded that dependent medical care should be supplied by the military organization and that pay increases or insurance coverage for dependents, as suggested by private physicians, should not be initiated. Also the commission recommended that in areas of hospital congestion Veterans Administration and Public Health Service facilities should be utilized for dependents. Furthermore, it was recommended that dependents living within 25 miles of military establishments should be *required* to first seek aid at the military base, except in emergencies!

The commission proposed that if military facilities are not available dependents should be given certificates of eligibility to be presented to civilian doctors or agencies. Payment would be made by the appropriate military department. As a restraint on excessive demands for medical attention, the commission recommended that the patient be charged the first $10 for each visit and 10% of the total bill for hospital and medical care. These restraints, you understand, would apply only in cases in which military hospital and medical care would be unobtainable or when dependents live more than 25 miles from a military establishment. Among other recommendations made by the commission, including definitions of illnesses to be included and excluded and restrictions on dental treatment, is a proposal that a separate budget be prepared by the Department of Defense for the care of military dependents.

Although the American Medical Association has n as yet, taken any official action with respect to the co mission's report, I have a few personal comments make on it. It appears that, although an attempt w made by the Secretary of Defense to appoint a comm sion of persons having no connection with the arm forces, the underlying theory of this a proach was defeated by the selection a military staff. It is not surprising, the fore, to find that the report approac the problem in question entirely fr the viewpoint of the armed forces, wi little or no regard for the recommen tions of interested civilian organizatio

To mention a few of the commissio omissions: There was no considerati given to the basic justification for dra ing physicians to supply medical care civilians, no study made of the possib ity that this program poses a threat federal control over medicine, and study made of the feasibility of tra ferring medical care for military d pendents into civilian channels. The la ter move would permit a free choice physicians and certainly would sa the government considerable mone It would seem that the major emphasis of the Moult commission was on justification and expansion of t present system, rather than on the consideration of a d ferent approach and possible curtailment.

Assuming that the continuation, or even expansion, the dependent medical care program is desirable, it is e tremely difficult to understand why the provision of su care in military facilities is necessary. It has always be the A. M. A.'s belief that civilian facilities, if availab and adequate, should be utilized first and that the use military facilities should be restricted to emergency sit ations and remote areas. This philosophy will be com pletely reversed if the recommendations of the Moulto commission are accepted. This is a subject that I pe sonally feel warrants the serious consideration of th newly appointed "Hoover commission."

I regret that because of space limitations I was able t give you only a partial analysis of the Moulton commis sion report. But I am told that a more detailed analysi will be published in THE JOURNAL in the near futur Please give it your most careful consideration when appears.

EDWARD J. MCCORMICK, M.D., Toledo, Ohio

ORGANIZATION SECTION

DEVELOPMENT OF UNIFORMITY IN MEMBERSHIP REGULATIONS BETWEEN CONSTITUENT ASSOCIATIONS AND THE A. M. A.

Prepared by Frank V. Cargill, Director, and Rose Tracy, Department of Records and Circulation.

The secretary of a midwestern constituent medical association recently urged that a concerted effort be made to develop uniform membership regulations and terminology between the various constituent associations and the American Medical Association as an important development of the program of intraprofessional relations. The need for a movement toward uniformity is apparent from the accompanying table, which correlates the classes of membership in the constituent associations with membership in the A. M. A. A survey made of other regulations covering transfers of membership, delinquency policies, billing procedures, and benefits and privileges of members shows further points of divergence.

Variety of Membership Terms

The table on page 1180 shows the 32 terms used by constituent associations to designate membership and the relationship of these types of membership to the two principal types of membership in the A. M. A.—active membership and associate membership. The A. M. A. also has three other types of membership—affiliate, honorary, and service—but these types are not dependent on membership in the constituent association.

In the table, a star indicates types of membership that permit a member to vote and hold office in his constituent association; such members are eligible to Active membership in the A. M. A. A cross on the chart indicates types of membership that do not permit a member to vote and/or hold office in his constituent association; such members are eligible only to Associate membership in the A. M. A.

There is not only a bewildering array in the table of nearly similar classifications, such as "retired" and "inactive," "military," "government service," "service," and "veteran," "emeritus," "life," "50-year club," "gold star," "senior," "honor," and "honorary," but also the privileges associated with such classifications vary from state to state. Most of the "life" members, as shown in column 15 of the table, can hold Active membership in the A. M. A.—except the "life" members in two states. In four states the "emeritus" classification entitles members to Active membership in the A. M. A., but in four other states "emeritus" classifications entitle members only to associate membership in the A. M. A. Even the use of the term "associate membership" lacks uniformity, with the table indicating in column 7 that one state gives the privileges of active membership to its associate members, entitling them to vote and hold office.

Further confusion arises from the constituent associations' use of "affiliate," "honorary," and "service" classifications, which entitle members to either active or associate membership in the A. M. A., but which have no relationship to affiliate, honorary, or service membership in the A. M. A. itself. The latter types of A. M. A. membership are not based on membership in the constituent associations, and are intended for physicians not otherwise eligible to A. M. A. membership through the constituent associations. It is conceded that much of the confusion concerning types of members has been a direct result of the changes made in the membership structure of the A. M. A. itself since 1950. Many physicians who were formerly Fellows of the A. M. A. still do not realize that this classification was discontinued by action of the House of Delegates at the June, 1952, Chicago Meeting, and that the present classification of active member includes the privileges formerly associated with fellowship.

Effect on Apportionment of Delegates

With representation in the A. M. A. House of Delegates based on the constituent association's number of active A. M. A. members, the type of membership held becomes extremely important in determining the member's liability for the payment of A. M. A. dues or his qualification for waiver of dues. To some extent, the A. M. A. policy of granting exemption from the payment of A. M. A. dues to active members of constituent associations who have been wholly or partially exempted from the payment of state and local dues during postgraduate training within five years of graduation, temporary military service, retirement, financial hardship or disability, or after the age of 70, may have spurred the creation of such classifications in the constituent associations as "retired," "inactive," "intern," "residency," "government service," and "military service." If so, the development has been a movement in the opposite direction needed.

Rather than create new classifications of membership to provide for such exemptions, it might have been better to have amended the constitution and by-laws of the constituent associations in such a way that the member retained the privileges of his active type of membership but was excused from the payment of dues for various reasons given by the A. M. A. In some states, the only types of membership available to physicians who are in postgraduate training, military service, or have retired are classifications that do not carry with them the right to vote and hold office. Therefore, such physicians are eligible only to associate membership in the A. M. A. and cannot be counted in the apportionment of delegates to the A. M. A. House of Delegates.

Standardization of Classifications in Constituent Associations

As shown in the table, the number of membership classifications in the constituent associations vary from a single classification in two states to eight classifications in one state. Fourteen states have only one type of membership eligible to active A. M. A. membership, and one state has six such classifications; 10 states have only one type of membership eligible to associate A. M. A. membership, and three have the maximum of five such classifications. The average number of membership classifications among the constituent associations is four (with an average of two classifications eligible to active A. M. A. membership and two eligible to associate A. M. A. membership), as shown in the table. Perhaps the first move toward simplification of membership terminology might be made in standardizing the names of four membership classifications, into one of which each member of a constituent association could fit without being subjected to changes in privileges or assessments.

From the standpoint of clarifying eligibility to A. M. A. membership, it is suggested that (1) the term "active member" be adopted by the constituent associations to designate the dues-paying member who has the right to vote and hold office; that (2) the term "emeritus member" be used for the member who pays no dues, or pays reduced dues, but retains the right to vote and hold office; that (3) the term "associate member" then be reserved by the constituent association for dues-paying members who do not have the right to vote and hold office; and (4) possibly the term "affiliate member" be used to designate the remaining non-dues-paying classifications, such as nonresident members, and distinguished out-of-state physicians, who cannot vote and hold office. The physicians in groups 3 and 4 would be eligible only to associate membership in the A. M. A.

Obviously, the foregoing proposal is not so easy to adopt as it sounds. Some of the classifications have been in use for decades and have meaningful connotations to the medical profession in the area. Nevertheless, it is hoped that each constituent association will carefully consider this proposal in the light of providing the greatest good to the greatest number and actively participate in the movement to standardize membership terminology. Actually, the problem goes down to the

Membership in Constituent Associations as Related to A. M. A. Membership

---

★ = can vote and hold office in state society (entitled to Active Membership in American Medical Association).

+ = cannot vote and hold office in state society (entitled to Associate Membership in American Medical Association).

▲ A. M. A. Membership is mandatory.

1. May vote and hold office if they maintain membership in county society.
2. All dentists.
3. Can vote, but cannot hold office in state society.
4. Available to colored physicians in state.
5. Membership only in county society; does not confer membership in state society.
6. Associate Members can vote and hold office if they have had 30 years' service in state association; Associate Members cannot vote and hold office if they have had less than 30 years' service in state association.
7. When given to nonmembers, does not include right to vote and hold office.

county level, because the component societies are the sole judges of membership, and, in many cases, they have created types of membership that have no standing in the constituent association and therefore no standing in the A. M. A.

Uniform Treatment of Transfers in Membership

Efforts are also needed to bring about uniformity in the treatment of transfers from one constituent association to another, in establishing delinquency dates, in billing for A. M. A. dues, and in handling exemptions from the payment of such dues. The physician moving his practice from the jurisdiction of one constituent association to another will find, oftener than not, that he will have to pay dues in the new association as well as in the old—only 25 of the constituent associations accept transfers of paid members from other associations without further payment of dues for the year—the other 27 associations require payment of dues in the new state as well as in the old state.

In most states, too, the newly located physician discovers that action on his application for membership can be taken only after a waiting period. The period varies with the component societies' regulations, the physician sometimes thereafter being immediately eligible to membership in the constituent association. In answer to a question on this subject, a number of associations stated that applicants for membership might have to wait 30 to 60 days for acceptance, while other associations indicated that the wait might be six months, one year, or even two years.

The transfer of membership thus becomes a perplexing problem for the physician who wishes to retain active membership in the A. M. A. but cannot promptly obtain membership through the component and constituent societies in the area to which he has moved. The problem, complicated by the fact that many component societies do not meet monthly, especially during the summer, is one that can be worked out only by the constituent association and its component societies.

Delinquency Dates in the Payment of Dues

Of a similar type is the problem of establishing a more nearly uniform date on which a member of the constituent association is regarded as delinquent in the payment of dues. The dates now used vary from Dec. 5 preceding the year for which dues are payable, to two years following the Jan. 1 on which payable. Six associations require payment on or before Jan. 1; 32 set dates from Feb. 1 to June 1; 3 societies have a delinquency date of July 1; 8 give the physician the full year in which to pay; and one gives two years before declaring the member delinquent.

The variation in dates in the constituent association adds further complication to the collection of A. M. A. dues. In nine states, a physician is required to hold membership in the A. M. A. if he wishes to hold membership in the constituent association. In these states, the date of delinquency does precede the date of delinquency specified in the bylaws of the A. M. A.; even in these states, however, the physician may not be officially dropped from membership until several months later. In many of the other states, the delinquent member's name is not removed from the membership roster until the end of the year; in a few states, his name is removed from the roster during the first month of the current year.

Considerable criticism could be made, it is admitted, of the present policy of the A. M. A., which has a theoretical delinquency date of June 1. Because there have been so many changes in the membership structure, action has been delayed as long as possible to give the physicians an opportunity to clear their payments through the constituent associations before their names had to be taken off the A. M. A. membership roster. Physicians have often delayed payment of dues because of misunderstanding or confusion, and rather than take these names off the roster in a summary manner, we have withheld action and frequently written three or four letters in order to clarify their membership status.

Collection of A. M. A. Dues

The constituent associations have also set up varying procedures to handle the collection of A. M. A. membership dues. In most states, dues are collected through the component societies, but in 12 states they are billed by the constituent associations direct to the member, although, in several of these states, the *state* dues are collected by the component societies. Even when A. M. A. dues are billed by the constituent association, they are, in four states, not billed until at least 30 days after dues in the constituent association have been billed. There are advantages in each method of collection; but, from the standpoint of avoiding duplication of effort (both in billing and sending a remittance) it would seem desirable, whenever possible, to incorporate in a single bill the annual membership dues of component society, constituent association, and the A. M. A., or at least to mail such bills at one time.

Confusion Over Exemption Policies

One further area in which greater uniformity should be achieved is in the regulations governing the exemption from payment of membership dues. The Bylaws of the A. M. A. provide that active members may be excused from the payment of A. M. A. dues for the following reasons: financial hardship or illness, retirement from active practice, postgraduate training within five years of graduation, temporary military service, and past the age of 70. To be eligible to exemption under the first three reasons, the member must also be wholly or partially excused from the payment of dues in the component society and the constituent association.

Misunderstanding concerning exemptions arise especially because of the confusion of service membership with exemption based on temporary military service. This type of exemption is given only to medical officers serving temporarily in the Army, Navy, or Air Force. Since July 1, 1952, by federal law, the United States Public Health Service is no longer a part of the armed forces, and exemptions cannot be granted to physicians in this service. Some constituent associations give a type of non-dues-paying membership to such physicians as well as to physicians in the Veterans Administration, the U. S. Civil Service, the Coast Guard, and other federal agencies, but similar exemptions cannot be given by the A. M. A.

Delay in granting exemption from the payment of dues occurs, with resulting confusion, when requests for exemption are received direct from the component societies on behalf of their members. Official action cannot be taken until the request has been processed by the constituent association. Conversely, when exemptions have been requested by members in correspondence with the A. M. A., there is frequently delay in clearing the exemption because our request to the constituent association is returned with the notation that information has not been received from the component association concerning the member's status.

The policies governing the exemption on the basis of temporary military service vary with respect to dates effective. In some states, the physician entering on active duty pays dues for the current year and his exemption begins the Jan. 1 of the following year; the A. M. A., however, exempts such members for the period beginning Jan. 1 or July 1 following the date of the member's entrance into the service.

A further study of the classifications of membership in the constituent associations, in relation to provisions exempting physicians from the payment of A. M. A. dues is being made, and a chart outlining the information will be available at a future date. Complete uniformity in all phases of membership probably will never be achieved, but a concerted effort on the part of constituent associations and component societies to develop uniform membership regulations and terminology will be a long step forward in advancing intraprofessional relations.

SUMMARY OF FEDERAL MEDICAL LEGISLATION

Prepared by the Washington Office of the American Medical Association.

The 83rd Congress convened Jan. 3, 1953, and adjourned *sine die* Aug. 3, 1953. During this period 10,695 legislative measures were introduced in the Senate and House. All of these were carefully screened for possible medical significance, and 274 were analyzed and reported by the Washington Office of the American Medical Association. This is 24 more than were followed by us in the entire two-year period of the 82nd Congress. The chief legislative measures are briefly summarized below.

Numerically, the commonest measures of interest to the medical profession as such were those dealing with social security and public assistance. Of 56 such measures, none became public law. In the research and aid programs, 37 measures were introduced. None of them became public law, and hearings were held only on the measures that would establish an independent agency for the handicapped. Identical bills to establish such an agency were introduced by Congressmen Hagen (H. R. 2096); Kelley (H. R. 3177); Perkins (H. R. 3188); Celler (H. R. 3291); Doyle (H. R. 3473); and Donohue (H. R. 4262).

Veterans' legislation was again prominent in a variety of proposals taking the form of 34 legislative measures. Only one, H. R. 5636, by Congressman Radwan, became law (Public Law 241), on Aug. 8. This lengthened the presumption of service connection for all types of tuberculosis to three years following military service. Congresswoman Rogers proposed an investigation of the Veterans Administration by the House Veterans Affairs Committee in H. Res. 34. This measure passed the House on March 5, and an appropriation of $50,000 was voted on March 16. Medical deductions in tax computation were proposed in 29 measures. Public hearings held in connection with general tax revisions included testimony supporting legislation of this type. The Teague proposal (H. R. 6015) would establish priorities for admission of patients with non-service-connected cases favoring chronic or long-term ailments.

There were 25 proposals dealing with military medicine. Of these, 10 were incorporated in the amended "Doctor-Draft" act, which became Public Law 84 on June 29. This act as amended was extended two years to July 1, 1955, including an extension of the $100 a month equalization pay for physicians and dentists.

Measures to reorganize the executive department of the government numbered 14; of these, 5 became public law. Congressman Hoffman of Michigan in H. J. Res. 223 made effective within 10 days the reorganization of the Federal Security Agency into the Department of Health, Education, and Welfare. This bill was passed by the House March 18, by the Senate March 30, and became Public Law 13 on April 1, 1953. A new "Hoover" commission on the organization of the executive branch of the government was created in S. 106 by Senator Ferguson, and H. R. 992, a companion bill, by Congressman Brown. These became Public Law 108 on July 10. A Commission on Intergovernmental Relations was created by S. 1514, introduced by Senator Taft and H. R. 4406, introduced by Congressman Halleck. These became Public Law 109 on July 10.

There were 11 proposals having to do with treaty regulations, most of them similar or identical with S. J. Res. 1 by Senator Bricker and 63 other Senators. Public hearings were held over a period of several weeks, and the measure was favorably reported to the Senate by the Judiciary Committee on June 15, but was not put on the Senate calendar and was not referred to a committee. His proposal places less restrictions on the executive branch than does the Bricker proposal.

Drugs and drug addiction were the subject of 10 measures. Six of these concerned factory inspection by federal food and drug agents and became Public Law 217 on Aug. 7. A variety of national health programs was proposed in 10 measures. These included compulsory health insurance, loans to cooperative and nonprofit health insurance associations, federal aid to voluntary health plans, and medical education. There were no hearings or action on any of these bills. An extension of the Hill-Burton Hospital Construction Act until 1957 was proposed by Senators Taft and Hill and by Congressman Harris and became Public Law 151 on July 27. A proposal by Congressman Judd to transfer the administration of Indian hospitals to the Public Health Service was reported favorably by the House Committee on Interior and Insular Affairs on July 17 but was not voted on. Ten measures in all were presented concerning hospitals.

Tax deductions for pension plans were proposed in seven measures. These bills, which would permit tax postponement for the self-employed to assist in the creation of annuities, were discussed at public hearings on Aug. 12 and 13, after the adjournment of Congress. No other action has been taken on these measures. Federal aid for medical education was presented in eight measures. Senator Hunt, in S. 1515, proposed to give authority to certain western states to form an interstate commission for jointly supporting higher education (without federal financial participation). This measure became Public Law 226 on Aug. 8. Among the types of higher education could be medicine and dentistry. Senator Taft in S. 1748 would grant a federal charter for the National Fund for Medical Education. This fund at present is operating under a New York state charter. The American Medical Education Foundation has worked in close cooperation with the national fund. The Taft measure was passed by the Senate on July 6, but the House did not vote on it. None of the other medical education aid bills were discussed in hearings or presented to either House for floor action.

The appropriation ceiling was removed from the National Science Foundation by H. R. 4689 by Congressman Wolverton and the companion bill, S. 977, by Senator Smith of New Jersey and Senator Aiken. These became Public Law 223 on Aug. 8. A House Select Committee to investigate educational and philanthropic foundations was enacted by H. Res. 217 by Congressman Reese. The House voted $50,000 to finance this study. Congresswoman Church in H. R. 116, and Senator Bridges in S. 2245, proposed to prohibit the transportation of fireworks into states where their sale was prohibited by state law. This measure was passed by the House on July 20 and favorably reported by the Senate Judiciary Committee on July 30, but not voted on.

A number of miscellaneous measures were proposed, but no hearings were held and no votes taken on them. They included measures to give aid to health and safety instruction in public schools, to provide for research in child life, to abolish the Bureau of Indian Affairs, to create a U. S. Medical and Dental Academy, to provide federal aid to states for industrial safety, to allow professional education expense deductions from income, to give federal aid to states for ambulance service; to allow freedom to select physician under longshoremen's and harbor workers' compensation act; to establish a joint congressional committee on science. Measures not passed by this first session of the 83rd Congress may be considered when Congress reconvenes and are not dead.

NEW A. M. A. PUBLICATIONS

The A. M. A.'s Committee on Pesticides recently compiled a new list of available publications. The titles include "Accidental Poisoning in Children," "Health Problems of Insecticide Vaporizing and Fumigating Devices," "Toxology in Medical Curriculum," and "Use and Abuse of Generic Names for Pesticides."

MEDICAL NEWS

CALIFORNIA

Ophthalmologic Conference.—The University of California Medical School will hold an ophthalmologic conference Dec. 2-5 at the University of California Medical Center and University Extension Building, 540 Powell St., San Francisco. Dr. Frederick C. Cordes is chairman of the course, and Dr. Peter C. Kronfeld, Chicago, will deliver the eighth Francis I. Proctor lecture, "Delayed Restoration of the Anterior Chamber," during the conference. Arrangements have been made this year so that each group will get one session of animal surgery. The course is open only to graduates of medical schools approved by the A. M. A. Council on Medical Education and Hospitals. The fee is $75.

Pediatric Seminars.—The alumni committee of the Children's Hospital, San Francisco, has announced the following pediatric seminars:

Dec. 5, Surgery and Anesthesia in Childhood, with a discussion on the effects of hospitalization for surgical procedures on the young child.
Jan. 23, 1954, Problems of Prematurity and the Newborn Infant.
March 30, Acute and Chronic Infections and the Choice of Antibiotics in Treatment.
April 24, Childhood Ecology, with a discussion of physical, mental, and emotional growth and development of the young child, the effects of deprivation of maternal care, and the impact of environment on the child.

A fee of $15 will be charged for attendance. Details may be obtained from Dr. Hulda E. Thelander, Children's Hospital, 3700 California St., San Francisco.

CONNECTICUT

Society News.—The New Haven Medical Society will have as speaker, Dec. 2, Dr. Elmer Alpert, chief of clinical research, Merck and Co., Inc., Rahway, N. J., whose subject will be "Present Status of Cortisone and ACTH Therapy."

Hospital Lectures.—The Hartford Hospital announces the following presentations in its Saturday morning 11 o'clock series:

Dec. 5, Averill A. Liebow, New Haven, Clinical Pathological Conference.
Dec. 12, Harold M. Marvin, New Haven, Observations on Aortic Stenosis.
Dec. 19, E. Myles Standish, Hartford, Dermatology (Kodachrome Presentation).

DISTRICT OF COLUMBIA

Federal Grant for Teaching.—The George Washington University School of Medicine, Washington, has received a $25,000 grant from the Public Health Service's National Heart Institute for use in teaching medical students the latest methods in diagnosing and treating heart diseases. The grant will be administered under the direction of Drs. Jack M. Evans, associate clinical professor of medicine, and Albert D. Kistin, associate in medicine.

District Society Honors Theodore Wiprud.—At its annual scientific assembly in the Hotel Statler, Washington, Oct. 7, the Medical Society of the District of Columbia presented a special certificate to Theodore Wiprud, executive director and secretary, "in recognition of his more than twenty-five years of service to American medicine and, in particular, of his fifteen years of steadfast devotion to the medical profession of the District of Columbia; and in further recognition of his accomplishments as an able administrator and author-editor; a teacher; a leader in civic life; friend of physicians; and in special and grateful appreciation of those moral and spiritual qualities that have characterized all his achievements —loyalty, sympathy, wisdom, unselfishness, and unsurpassed honesty." Mr. Wiprud came to the society in 1938 after serving for 10 years as executive secretary of the Medical Society of Milwaukee County in Wisconsin.

FLORIDA

Obstetric and Gynecologic Society.—The midwinter meeting of the Florida Obstetric and Gynecologic Society will be held at the Orange Court Hotel in Orlando, Dec. 5-6. The program will be presented by Dr. Frank R. Lock, professor of obstetrics and gynecology, Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, N. C., Dr. Robert B. Greenblatt, professor of endocrinology, Medical College of Georgia, Augusta, and Dr. W. Nicholson Jones, professor of gynecology, Medical College of Alabama, Birmingham.

GEORGIA

Narcotic Violation.—Dr. William Henry Wall, Blakely, pleaded not guilty in the U. S. District Court at Albany to a violation of the federal narcotic laws and on Oct. 8 was found guilty and sentenced to serve a term of 18 months.

Cardiovascular Research.—Chairs for cardiovascular research at Emory University School of Medicine, Atlanta, and the Medical College of Georgia, Augusta, were recently made possible by identical grants of $12,000 to each school by the Georgia Heart Association. Occupants of the chairs will be full-time faculty members of the medical schools and directors of research laboratories bearing the name of the heart association. The association plans to repeat the grants on an annual basis, and the schools are adding $3,000 to the amount of the grant. The school will have full authority in the selection of the person.

Personal.—Dr. Hal M. Davison, chief of medicine, Georgia Baptist Hospital, Atlanta, has been elected a co-chairman of the Atlanta round table of the National Conference of Christians and Jews. He is a past president of the Fulton County Medical Society.——By invitation of the Scottish Nutrition Society and the Royal College of Physicians of Edinburgh, Dr. Virgil P. Sydenstricker, professor of medicine, Medical College of Georgia, Augusta, presented a paper, "The Impact of Vitamin Research on the Practice of Medicine," at the bicentenary celebration of the publication of Lind's "Treatise of the Scurvy." Dr. Sydenstricker had previously been awarded the King's medal by the United Kingdom. He was also the memorial orator for the Robert Campbell lecture, after which Queen's University of Belfast presented him with a medal. ——Dr. Robert B. Greenblatt, professor of endocrinology, Medical College of Georgia, Augusta, served as moderator of the panel discussion, "Disorders of the Adrenal Cortex," at the postgraduate course in endocrinology and metabolism, sponsored by the University of Minnesota Medical School at Minneapolis from Sept. 28 to Oct. 3.

ILLINOIS

Quarantine for Rabies.—Bloom township was placed under a rabies quarantine by the state department of agriculture after four persons were bitten by rabid dogs early in October. Thorntown township, north of Bloom township and about 16 miles south of Chicago, has been under a similar quarantine since May.

Society News.—At a meeting of the Otolaryngologic Alumni Association of the University of Illinois in Chicago Dr. Albert H. Andrews Jr., clinical assistant professor of bronchoesophagology, was elected president and Dr. Burton J. Soboroff, Chicago, reelected secretary-treasurer. The association presented an engraved silver cigaret box to Dr. Francis L. Lederer, Chicago, named the outstanding teacher during the

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

1952-1953 school year. Dr. Cecil D. Riggs, captain in the Medical Corps, U. S. Navy, was presented *in absentia* with a similar award as the outstanding resident during the school year.

Chicago

Dickinson Memorial Lecture.—The second Albert Dickinson memorial lecture, "Nutritional Interrelationships," was given by Conrad Arnold Elvehjem, Ph.D., dean of the Graduate School of the University of Wisconsin, in the Chicago Academy of Sciences, Nov. 20 at 8 p. m.

Dr. Kampmeier Goes to California.—Dr. Otto F. Kampmeier, professor of anatomy, University of Illinois College of Medicine, since 1928, has been appointed head of the department of anatomy at the College of Medical Evangelists, Loma Linda, Calif. Dr. Kampmeier, who came to the University of Illinois as instructor in anatomy in 1918, was made head of the department in 1929. He had been affiliated with the University of Pittsburgh from 1912 to 1918.

Meeting on Poliomyelitis.—At a meeting of the North Side branch of the Chicago Medical Society in the Drake Hotel, Dec. 3 at 8 p. m., "The Changing Front of Research in Poliomyelitis" will be presented by Dr. Hart E. Van Riper, medical director, National Foundation for Infantile Paralysis, Inc., New York, and Dr. Henry W. Kumm, the foundation's director of research. Discussants will be Howard J. Shaughnessy, Ph.D., head of the department of public health, University of Illinois College of Medicine, and deputy director, Illinois Department of Public Health, division of laboratories, Chicago; Dr. Leonard M. Schuman, deputy director, Illinois Department of Public Health, division of preventive medicine, Springfield; and Dr. Sidney O. Levinson, director, Michael Reese Research Foundation, Chicago. The program will be preceded by a fellowship gathering, 5:30 p. m., and dinner, 6:30 p. m. For reservations, call CEntral 6-7764.

KANSAS

Cancer Institutes.—The following tentative dates have been announced for a series of cancer institutes for nurses, sponsored by the Kansas League of Nursing, the Kansas division of the American Cancer Society, and the division of geriatrics and chronic diseases and public health nursing services of the Kansas State Board of Health: Nov. 30, Dec. 1-2, Hays; Dec. 2-4, Wichita; Dec. 8-10, Kansas City; and Dec. 14-16, Topeka.

MASSACHUSETTS

House Officers' Lecture.—The House Officers' Association, New England Center Hospital, Boston, announces that on Dec. 1 at 7 p. m. Rosalind Pitt-Rivers, Ph.D., London, England, will discuss "Triiodothyronine and Thyroid Function" in the Stearns Auditorium of New England Center Hospital. All interested persons are invited.

University Retirements.—Dr. C. Wesley Sewall, head of the department of obstetrics, and Dr. Samuel R. Meaker, professor of gynecology, Boston University School of Medicine, have retired after 33 and 31 years of service, respectively. In World War I, Dr. Sewall served as captain in the U. S. Army Medical Corps and Dr. Meaker served in the Royal Army Medical Corps.

Emergency Library for Korean School.—At a ceremony on Sept. 23 in the Harvard School of Public Health, Boston, Brig. Gen. James Stevens Simmons, U. S. Army, retired, dean of the Harvard School of Public Health, presented to Mr. Pyo Wook Han, counselor of the Korean Embassy, an emergency library of more than 300 public health and preventive medicine texts and reference books for use in the new Seoul National University School of Public Health, South Korea's first school of public health. The books, collected at the request of Col. James P. Pappas, chief of the public health section of the United Nations Civil Assistance Command in South Korea and a graduate of the Harvard School of Public Health, were sent by air to Seoul by the American-Korean Foundation.

MICHIGAN

Television Course for Parents.—The University of Michigan Medical School, Ann Arbor, will conclude its series of television programs on the growing baby with its program on Dec. 6, in which Dr. Ralph D. Rabinovitch, associate professor of psychiatry and chief of the children's service, Neuropsychiatric Institute, will present "Your Child's Behavior." (For stations, see THE JOURNAL, Oct. 17, p. 649.)

MINNESOTA

Dr. and Mrs. Mayo Honored.—Dr. and Mrs. Charles W. Mayo, Rochester, were guests at a dinner in Minneapolis, given by the Minnesota United Nations Association, Aug. 24, in honor of his recent appointment as alternate delegate to the United Nations Assembly and of Mrs. Mayo for her service as a member of the board of directors of the Minnesota United Nations Association.

MISSISSIPPI

Rabies in Man.—According to the Department of Health, Education, and Welfare, U. S. Public Health Service, a man was bitten on the hand by one of two family dogs in June but did not seek treatment. The dog disappeared. On July 4 a son of the victim was bitten by the other dog whose brain, on examination at the state laboratory, showed Negri bodies. The child promptly received rabies vaccine and up to the time of report (late September) had escaped the disease. The man died, and examination of his brain confirmed the diagnosis of rabies.

Conference on Alcoholism.—The University of Mississippi in University announces that an Alcohol Studies Conference will be held at the university, Dec. 4-5, under sponsorship that includes 30 mid-south medical, business, and social organizations. Speakers will include Anton J. Carlson, Ph.D., professor emeritus of physiology, University of Chicago, Dr. Thomas L. Young of Mississippi State Hospital, Whitfield, Dr. Frank A. Latham of the Carrol Turner Sanatorium, Memphis, and Dr. David S. Pankratz, dean of the school of medicine. The public is cordially invited.

MISSOURI

Terry Lecture.—The annual Robert J. Terry lecture, "The Search for Man's Ancestors," will be delivered by William L. Straus Jr., Ph.D., professor of physical anthropology, Johns Hopkins University, Baltimore, before the St. Louis Medical Society at 8:30 p. m., Dec. 1, in the Medical Society Auditorium, 3839 Lindell Blvd.

NEW YORK

Institute of Cytology.—An institute of cytology was recently established at Beth-El Hospital, Brooklyn. The department will emphasize the diagnosis of cancer in the early stages of development before the appearance of symptoms and will conduct research studies of the relationship of the endocrine glands to cancer of the female reproductive system.

Dr. Coughlin Goes to Indonesia.—Dr. Frank E. Coughlin, Rensselaer County commissioner of health, has resigned from the board of health to accept a position in Indonesia as chief of public health in the Technical Cooperation Administration. He will serve for two years as adviser on all public health problems to the Republic of Indonesia. Dr. Coughlin's successor is Dr. Andrew C. Fleck of Troy, who joined the staff of the state health department in March, 1949.

Course on the Office Laboratory.—The University of Buffalo School of Medicine announces a postgraduate course (Dec. 3) on the office laboratory. Since the course is primarily oriented toward increasing the physician's understanding of modern laboratory procedures, the office technician may attend with, but not in place of, the physician. Presentations will include basic techniques, urine analysis, use of photoelectric colorimeter, blood chemistry, and coordination with the hospital laboratory. A concise laboratory manual will be made available to registrants. The fee of $15 should accompany application to Dr. Milton Terris, Assistant Dean for Postgraduate Education, University of Buffalo School of Medicine, 3435 Main St., Buffalo 14. Sessions will be held in Room G22, Capen Hall.

Personal.—Dr. Thelma S. Miner, Jamestown, was recently appointed district health officer in the Watertown area.——Dr. Harry Wexler, attending pediatrician, Maimonides Hospital, Brooklyn, recently received a New York University 1953 alumni meritorious service award for "distinguished service to the university." Dr. Wexler, who is currently chairman of the Parents' Association, New York University College of Medicine, has created a student aid and scholarship fund and has established the Harry Wexler Endowment Fund at the college.——Dr. William R. Donovan, Geneva, has been appointed director of the White Plains regional office, State Department of Health. Dr. Donovan, who has been district state health officer in charge of the Geneva district since June, 1947, has also been serving on a part time basis as acting health commissioner of the newly organized Seneca County Health Department since July 1, 1950.——At the ninth convention of the International Society for Speech and Voice Science, in Zurich, Dr. Emil Froeschels, New York, was elected honorary president of the society for life.——Dr. Raphael O. Patt, Johnson City, has been named an assistant medical director of the American Heart Association. Dr. Patt was engaged in the practice of medicine in Johnson City for several years, during which time he was associated with the medical department of the Endicott Johnson Corporation. He has also been affiliated with Fairview Park Hospital, Cleveland, New Jersey State Hospital, Marlboro, N. J., and Jennings Memorial Hospital, Detroit.

New York City

Hospital News.—On Dec. 4 Dr. William Dameshek, director, Blood Research Laboratory, New England Center Hospital, Boston, will present "Polycythemia and Related Conditions" at 3 p. m. in the social hall of Montefiore Hospital for Chronic Diseases.

Lecture on Leukemia.—The fifth annual Louis Hauswirth lecture in medicine, sponsored by the Beth David Hospital Alumni Association, will be delivered by Dr. Nathan Rosenthal, consultant hematologist, Mount Sinai and Beth David hospitals, attending physician, Harlem Hospital, and formerly clinical professor in medicine, Columbia University College of Physicians and Surgeons, Dec. 2, at Beth David Hospital, 161 E. 90th St. Dr. Rosenthal's subject will be "Present Trends in the Treatment of Leukemia."

Cancer Society Meeting.—The New York Cancer Society will meet on Dec. 1 at 8:30 p. m. in the New York Academy of Medicine, Fifth Avenue at 103rd St., to consider "Prospects for Earlier Diagnosis of Cancer." The following program will be presented:

Prospects for Earlier Diagnosis of Gastric Cancer, William A. Cooper, New York; discussant, Paul C. Swenson, Philadelphia.
Prospects for Earlier Diagnosis of Cancer of the Prostate, William F. Boyer, Tulsa, Okla.; discussant, Victor F. Marshall, New York.
Studies of Breast Smears in Relation to Breast Cancer, George N. Papanicolaou, New York; discussant, Howard L. Richardson, New York.
Prospects for Earlier Diagnosis of Lung Cancer, William J. Tuddenham, Philadelphia; discussant, Ross Golden, New York.

Physicians and medical students are cordially invited.

Dr. Oliver Honored.—The president of the State University of New York has announced the appointment of Dr. Jean Redman Oliver, professor of pathology at the university, as the university's first distinguished service professor, "in recognition not only of his long service to the college of medicine but more particularly of the preeminent contributions he has made in the field of teaching and for his outstanding contributions as an investigator." Dr. Oliver has the longest record of service to the medical school of any full professor on the faculty. Dr. Oliver has reviewed his contributions to renal pathology in the Harvey lecture in 1944 and 1945, the Janeway lecture in 1948, and the Guiteras memorial lecture in 1950. In 1952 he was awarded the William Wood Gerhard medal, and last spring the Phi Lambda Kappa medical fraternity at the college inaugurated an annual lectureship "in honor of the man who has done so much to clarify the structural and functional aspects of kidney disease." Dr. Oliver has been affiliated with Stanford University School of Medicine, Stanford University-San Francisco, the Stanford University and San Francisco hospitals, Rockefeller Institute, and the Long Island College and Kings County hospitals in Brooklyn. He has recently been granted a leave of absence by the university to engage in research for the U. S. Army Epidemiological Board on renal lesions in epidemic hemorrhagic fever but will return to the college during the year to lecture to the students.

NORTH CAROLINA

Annual Duke Medical Symposium.—Duke University School of Medicine, Durham, will hold its annual medical symposium Dec. 1-2. Speakers will include: Dr. S. Spafford Ackerly, University of Louisville School of Medicine; Dr. Leo H. Bartemeier, Wayne University College of Medicine, Detroit; Dr. Frank J. Curran, University of Virginia Department of Medicine, Charlottesville; Col. Albert J. Glass, chief of neuropsychiatric services, Brooke Army Medical Center, Fort Sam Houston, Tex.; Dr. Roger W. Howell, University of North Carolina School of Medicine, Chapel Hill; Dr. William S. Kroger, Chicago Medical School; Dr. William T. Lhamon, University of Pennsylvania School of Medicine, Philadelphia; Dr. Theodore Lidz, Yale University School of Medicine, New Haven, Conn.; and Dr. Ralph D. Rabinovitch, University of Michigan Medical School, Ann Arbor.

OKLAHOMA

Appoint Director of Health Services.—Dr. Jean S. Felton, associate professor in the departments of medicine and preventive medicine and public health, University of Oklahoma School of Medicine, Oklahoma City, has been appointed director of health service of the university hospitals. Dr. Felton, who came to Oklahoma City from the Oak Ridge (Tenn.) National Laboratory after serving there as medical director for seven and one-half years, is establishing the medical school's first course in industrial medicine this fall. Dr. Felton has been appointed to the Oklahoma governor's committee to further the employment of the handicapped and has been named as a member of the correspondence committee on occupational safety and health of the International Labor Office. During World War II he was in charge of industrial medicine for the San Francisco port of embarkation.

OREGON

Dr. Kaufman Honored.—Following the outbreak of the Korean hostilities, Dr. Russell H. Kaufman, Portland, chairman of the committee on emergency medical service, Oregon State Medical Society, was awarded the National Freedoms Foundation's George Washington honor medal. Dr. Kaufman played a leading part in the development of the programs of the Oregon Civil Defense Agency and the Portland Disaster Relief and Civil Defense Organization, of which he is chairman of the physicians' section.

PENNSYLVANIA

Hospital News.—The Doylestown Emergency Hospital, said to be operated solely by women, has been bequeathed $125,000 in the will of Mrs. Kate Penrose Shuman of Doylestown, who died July 24 at the age of 99. The hospital recently completed another building program at a cost of $175,000.

University News.—Dr. William H. Ramsey, Bryn Mawr, has been appointed associate professor of surgery (proctology) at Hahnemann Medical College and Hospital of Philadelphia.

Dr. Ramsey is assistant surgeon to Pennsylvania Hospital, Philadelphia, and to Bryn Mawr Hospital and consulting surgeon to Veterans Administration Hospital, Philadelphia.

Philadelphia

Philips Lecture.—Dr. William P. Shepard, vice-president of the Metropolitan Life Insurance Company, New York, will discuss "Industrial Health" at Roberts Hall, Haverford College, on Dec. 1 at 11 a. m. This presentation is one of the William Pyle Philips series, "New Frontiers in Medicine."

Anders Lecture on Pituitary Infantalism.—The College of Physicians of Philadelphia announces the James M. Anders lecture at 19 S. 22nd St. on Dec. 2 at 8:30 p. m. Sir Geoffrey Jefferson, M.S. (London), F.R.C.S., emeritus professor of neurosurgery, University of Manchester, England, will present "Reflections on Pituitary Infantalism."

Television Programs.—In conjunction with the WFIL-TV University of the Air, members of the faculty of the Philadelphia College of Pharmacy and Science are presenting television lectures over that station, Channel 6, on Friday mornings, 11:15 to 11:33. The following programs are scheduled for December:

Dec. 4, Sources of Some Household Medicinals.
Dec. 11, The Frontier of Research on Cancer.
Dec. 18, Allergy and the Antihistamines.

RHODE ISLAND

Cancer Conference.—At the annual Cancer Conference for Physicians, held at Miriam Hospital in Providence under the auspices of the Rhode Island Medical Society, Oct. 14, the following program was presented:

Use of Radioactive Isotopes in Cancer, Joseph C. Aub, Boston.
Cancer of the Mouth, Ernest M. Daland, Boston.
Exfoliative Cytologic Method in the Diagnosis of Gastric Cancer (a motion picture).
Carcinoma-in-Situ, Richard W. TeLinde, Baltimore.
Surgical Treatment of Cancer of the Cervix, Alexander Brunschwig, New York.
Bronchogenic Carcinoma, Francis B. Berry, New York.
Carcinoma of the Colon and Rectum in Connecticut, Edward J. Ottenheimer, Willimantic, Conn.

Personal.—Dr. Henry H. Babcock, acting superintendent and physician-in-chief since May, 1951, of Butler Hospital, Providence, has been named permanently to that post by the board of trustees.——On behalf of the Jewish War Veterans, Governor Roberts recently presented Dr. Alexander M. Burgess with an award of merit for his work in the field of brotherhood. Dr. Burgess has served as physician-in-chief in three hospitals in Providence; served abroad in the Navy in World War I; as chairman of the Medical Teaching Mission to Germany in 1948; and for several years has been the Area Medical Section Chief at the Veterans Administration for New England and New York.——At commencement exercises, the Rhode Island College of Pharmacy and Allied Sciences conferred on Dr. Michael H. Sullivan the honorary degree of doctor of science. Dr. Sullivan has served the Newport Hospital as associate surgeon and chief of obstetrics and has been president of the Newport board of health since 1944. He was recently selected as practitioner of the year by the Rhode Island Medical Society.

TENNESSEE

University News.—Vanderbilt University School of Medicine, Nashville, has established a separate division of ophthalmology with Dr. Henry Carroll Smith, professor of clinical ophthalmology, as its head.——The U. S. Public Health Service has awarded grants totaling $45,012 to investigators at the University of Tennessee Medical Units, Memphis: $25,000 will be used to improve the teaching of cancer in the College of Medicine and $7,603, to familiarize the women of Shelby County with the current cervical cancer detection program. Dr. Cyrus C. Erickson, professor of pathology, was awarded $7,225 to conduct research on cancer of the cervix. Dr. Albert M. Hand, instructor in pathology, who is attempting to improve the treatment of phenomena in the newborn, was awarded a grant of $5,184.——The new Graduate Science Laboratory, a three story annex to the Vanderbilt University School of Medicine, Nashville, has been constructed at a cost of approximately $300,000 ($125,000 of which was supplied by a grant from the National Advisory Cancer Council) to provide a place where scientists in various fields may work together. It is planned that additional stories, from the fourth to the ultimate ninth, can be added one or more at a time, whenever they are needed to house appropriate research work. Among the contemplated projects is a study on metabolism employing radioactive isotopic tracers, a technique that will involve the departments of anatomy, biochemistry, biology, chemistry, mathematics, pathology, pharmacology, physics, and physiology.

TEXAS

Internists Meet in Houston.—The meeting of the Texas Academy of Internal Medicine, Dec. 5-6, at the Shamrock Hotel in Houston, will be preceded by a postgraduate course in endocrinology, particularly on the pituitary-adrenal aspects, Dec. 2-3, given in cooperation with the Baylor University College of Medicine. Dr. Jerome W. Conn, professor of medicine, University of Michigan Medical School, Ann Arbor, will be guest speaker. This course will be open only to members of the Texas Academy of Internal Medicine at a fee of $10. On Dec. 4, the Texas Rheumatism Association meeting will also be held at the Shamrock Hotel, with Dr. Edward W. Boland, Los Angeles, as guest speaker. By payment of a registration fee of $5 any member of the Texas Academy of Internal Medicine will be allowed to attend this program.

WEST VIRGINIA

Society News.—The West Virginia Trudeau Society has elected Dr. Hugh S. Edwards, Beckley, president, Dr. George F. Evans, Clarksburg, vice-president, and Dr. Haven M. Perkins, Charleston, secretary-treasurer.——All the present officers of the West Virginia Tuberculosis and Health Association were reelected at the annual meeting in Fairmont. Dr. Karl J. Myers, Philippi, is president, Dr. Harold H. Howell, Madison, vice-president, Mr. Lester Harer, Logan, secretary, and Mr. Robert C. Hawkins, Charleston, treasurer.

WISCONSIN

Proctology Course.—A postgraduate course in proctology is being offered at Marquette University Medical School, Milwaukee. The first session was held Nov. 25. Other meetings are scheduled for Dec. 2, 9, and 16, 4-5:30 p. m., closing with clinical sessions at the Milwaukee County Dispensary on Dec. 10 and 14 from 10:30 a. m. to 12 noon. The course, which is directed by Dr. Albert Schutte, assistant clinical professor of surgery, is accredited by the Academy of General Practice. Tuition fee is $25.

ALASKA

Personal.—Dr. Arthur N. Wilson has been appointed a member of the Alaska Board of Health to succeed Dr. Dwight L. Cramer, a member of the first board of health, whose current term expired in January. Both physicians are from Ketchikan. Dr. Asa L. Martin, Anchorage, is a hold-over member of the Board.

Alaska Territorial Medical Meeting.—The Alaska Territorial Medical Association at its annual meeting in Sitka elected Dr. Paul B. Haggland, Fairbanks, president; Dr. Asa L. Martin, Anchorage, first vice-president; Dr. John O. Bangeman, Wrangell, second vice-president; and Dr. William P. Blanton, Juneau, secretary-treasurer. Honorary memberships were conferred on the following guest speakers: Dr. Martin H. Seifert, Wilmette, Ill.; Dr. Vernon C. Turner, Evanston, Ill.; Dr. Lowell D. Snorf, Evanston; Dr. Franklin B. Peck, Indianapolis; and Dr. Caleb S. Stone Jr., Seattle. The 1954 meeting of the Alaska Territorial Medical Association will be held at McKinley Park, Alaska, Aug. 15-17. Visitors from the states are invited to attend this meeting and to make reservations directly with the McKinley Park Hotel.

GENERAL

Rheumatology Prize.—The Health Resort Office of Acqui in Italy announces that the closing date of the international competition, under the auspices of the Italian Society for Rheumatology, for the Acqui award for rheumatology (The Journal, July 11, p. 1056) has been extended from Jan. 31 to Feb. 28, 1954.

Society News.—At the annual meeting in Springfield the **American Medical Writers' Association** installed Dr. Jacob E. Reisch, Springfield, Ill., as president for 1954 and elected the following officers: president-elect, Dr. Lee van Antwerp, Skokie, who was also named editor; first vice-president, Dr. W. W. Bauer, Chicago; second vice-president, Dr. Stewart G. Wolf, Oklahoma City; accounting officer, Dr. Norbert C. Barwasser, Moline, Ill.; and secretary-treasurer, Dr. Harold Swanberg, Quincy, Ill.

Meeting on Alcoholism.—The fifth International Conference of Doctors in Alcoholics Anonymous will be held at the Mayflower Hotel in Akron, Ohio, May 14-16, 1954. Among the speakers will be Dr. Harry M. Tiebout, Greenwich, Conn., Dr. Arnold Z. Pfeffer, New York, chief of the Alcoholic Clinic at University Hospital in New York, and Seldon D. Bacon, Ph.D., of the Yale Foundation of Alcoholism. Information may be obtained from Dr. Herbert D. Chamberlain, McArthur, Ohio, or Doctors, care of the Mayflower Hotel, Akron, Ohio.

Anniversary Issue Dedicated to Dr. Cannon.—The September-October number of *Psychosomatic Medicine*, the 15th anniversary issue of the journal of the American Psychosomatic Society, is dedicated to the late Dr. Walter B. Cannon, who joined the faculty of Harvard Medical School, Boston, in 1899, in 1906 became head of its department of physiology, and in 1942 became emeritus professor of physiology. He was secretary of the A. M. A. Section on Pathology and Physiology, 1906-1908, and a member of the A. M. A. Council on Physical Therapy when it was created in 1925.

New Radiation Journal.—Academic Press, Inc., announces the completion of plans for a new journal, *Radiation Research*, the official organ of the Radiation Research Society, with Titus C. Evans, Ph.D., State University of Iowa College of Medicine, Iowa City, as managing editor. The journal will publish, bimonthly, original articles dealing with all phases of radiation research to promote the integration of the disciplines of physics, chemistry, biology, and medical research as they are concerned with the effects of radiation on matter. The first issue is scheduled for release in February, 1954. Information about subscriptions may be obtained from Academic Press, Inc., 125 E. 23rd St., New York 10.

Journal of Forensic Medicine.—With the July-September issue, a quarterly international medicolegal journal, *Journal of Forensic Medicine*, was launched under the sponsorship of the Medico-Legal Society (Johannesburg, South Africa). The first issue contains the following titles: "Blood Groups and Skin Colour," "Identification of Skeletal Remains," "Dentures and Individual Identification," "Sudden or Unexpected Deaths in Infancy," "X-Rays as an Aid to Medico-Legal Investigation," "Sudden Death with the Minimal Anatomical Findings," "Estimation of Structure from the Long Bones," and "Estimation of Age from Cranial Suture Closure." The address of the publication is P. O. Box 30, Cape Town, South Africa, and its editor is H. A. Shapiro, Ph.D., M.B., Ch.B., F.R. S.S.Af. The annual subscription rate is 42 shillings (approximately $6).

Life Expectancy Among Diabetics.—According to the Metropolitan Life Insurance Company, expectation of life among diabetics has increased substantially as a result of progress in the medical control of the disease and the introduction of insulin therapy. Their analysis of the experience among many thousands of diabetics treated at the Joslin Clinic in Boston showed that (1) no less than 35% of recently deceased patients had lived 20 years or more after onset of the disease, (2) the list of causes of death more and more resembles that among nondiabetics, and (3) diabetic coma was responsible for only 1% of the recent deaths. Death from infection, likewise, had been reduced to minor importance in the total mortality among diabetics. A major proportion of the deaths was accounted for by heart disease of the coronary type; the second largest cause, accounting for nearly one eighth of the deaths, was renal disease.

Goiter Association's Merit Award.—An anonymous gift of $1,000, to be awarded each year for three years, has been accepted by the executive council of the American Goiter Association. This sum shall be given to the member of the association under 45 years of age who has made the most important contributions to the knowledge and understanding of thyroid disease or its treatment. Candidates for the award are to be nominated by members of the association, who must submit (1) details of the nominee's present and past positions and training, (2) a bibliography of the nominee's publications, and (3) a full explanation of the reasons for the nomination. The award, which will be called the American Goiter Association Award of Merit, will be presented at the annual banquet. Two copies of nominations must be received not later than Feb. 1, 1954, by Dr. John C. McClintock, recording and corresponding secretary, 149½ Washington Ave., Albany 10, N. Y.

Osborne and Mendel Award.—Nominations are invited for the Osborne and Mendel Award of $1,000, established by the Nutrition Foundation, Inc. The award is given to the investigator who is judged to have made the most significant published contribution in the year preceding the annual meeting of the American Institute of Nutrition, or who has published a series of contemporary papers of outstanding significance. Preference will be given to research workers in the United States and Canada, but investigators in other countries, especially those sojourning in the United States or Canada, are not excluded from consideration. Membership in the institute is not a requirement for eligibility, and there is no limitation as to age. Nominations for the award, which may be made by anyone, should be sent before Jan. 1, 1954, together with data relative to the accomplishments of the nominee, to the chairman of the nominating committee, Herbert E. Robinson, Ph.D., Research Laboratories, Swift and Company, Union Stock Yards, Chicago 9.

Graduate and Postdoctoral Fellowships.—The National Science Foundation plans to award about 750 graduate and postdoctoral fellowships to persons planning to undertake graduate study in the sciences during the 1954-1955 academic year. Awards for graduate training will be announced March 15, 1954, and awards for postdoctoral training, April 1. Selection of persons for fellowships will be made from among citizens of the United States, solely on the basis of ability. Awards are not made to persons studying for the M.D. degree, but applications will be accepted from students who intend to obtain advanced training in one of the medical sciences directed toward a career in research. Persons now in college or graduate school should find application forms available through the office of their president, dean, or department head. Application forms also may be requested from the Fellowship Office, National Research Council, 2101 Constitution Avenue, N. W., Washington 25, D. C.

Conference on Diathermy Equipment.—The Federal Communications Commission, Washington 25, D. C., announces that, at the request of the Electro-Medical Manufacturers Association, a conference on regulation of medical diathermy equipment will be held, starting at 10 a. m. on Nov. 30 at the commission's offices. This conference is being called to discuss problems relating to the enforcement of Part 18 of the commission's rules governing the use of medical diathermy equipment, which became effective on June 15, 1947, but did not become applicable until June 30, 1953, to medical diathermy equipment manufactured and assembled before July 1, 1947. Part 18 now requires that all short wave medical diathermy equipment be of the type approved by the commission, certified by the manufacturer or a competent engineer, or licensed by the commission. All interested parties are invited to attend and are requested to send written notification to the chief engineer of the commission signifying their intention to be present.

Public Welfare Conference in Chicago.—The national biennial round-table conference of the American Public Welfare Association will convene at the Edgewater Beach Hotel, Chicago, Dec. 2-5. Round tables will include home medical care programs, structure and purpose of commissions on aging, cooperation in rehabilitation for handicapped persons, principles of medical and dental care programs for the needy, principles and problems of hospital payment, public welfare services to the aged, use of mental health resources, and the financing of hospital care for persons with low incomes. Panel discussions include "The Life Span" and "Current Issues in Social Security." The Hon. Harold E. Stassen, director, Foreign Operations Administration, Washington, D. C., will address the luncheon meeting Thursday, 12 noon to 1:45 p. m. The Hon. William G. Stratton, governor, State of Illinois, will present greetings at the conference banquet Friday, 7 to 10 p. m., and the Hon. Oveta Culp Hobby, secretary of health, education, and welfare, Washington, D. C., will deliver an address. John W. Tramburg, director, State Department of Public Welfare, Madison, Wis., will be the speaker for the closing general session, Saturday, 11:15 a. m. to 12:30 p. m.

Surgical Association Meeting.—The Western Surgical Association will hold its annual meeting, Dec. 3-5, at the Drake Hotel, Chicago, under the presidency of Dr. G. Lawrence Chaffin, Los Angeles. Papers presented by invitation include:

New Method for the Determination of Gallbladder Function, Lloyd A. Stirrett and Eric T. Yuhl, Los Angeles.
The Spleen—A Surgical Trouble-Maker, Stephen E. Reid, Evanston, Ill.
Use of Parasympatholytic Drugs in Treatment of Craniocerebral Injuries, Daniel A. Ruge, Chicago.
Leiomyosarcoma of the Inferior Vena Cava—Case Report, Joseph S. Cope, Kansas City, Mo.
Arfonad in General Surgery, Max S. Sadove, Gordon M. Wyant, and Gwen Gleave, Chicago.

By invitation 35 other speakers will participate in the presentation of the papers scheduled. A clinical day has been planned Wednesday by the local committee at the Veterans Administration Hospital, Hines, Ill., and the Research and Educational Hospitals, Chicago. Dr. Chaffin will deliver the presidential address, "Examinations by the American Board of Surgery," on Thursday. Cocktails in the French Room, 6:30 p. m., will precede dinner in the Gold Coast Room, at which Dr. Willis J. Potts, Chicago, will be toastmaster.

Van Meter Prize.—The Van Meter prize for 1953 was awarded to Dr. Belton A. Burrows, assistant professor, Boston University School of Medicine, for the essay (with Dr. Joseph F. Ross, associate professor of medicine), entitled "The Thyroidal Uptake of Stable Iodine Compared with the Serum Concentration of Protein-Bound Iodine in Normal Subjects and in Patients with Thyroid Disease." Drs. Burrows and Ross serve as senior physician and director, respectively, of the radioisotope unit, Veterans Administration Hospital, Boston. First honorable mention was given to the essay by Dr. Sidney H. Ingbar, Boston, entitled "Simultaneous Measurement of the Iodide-Concentrating and Protein-Binding Capacities of the Human Thyroid Gland." Dr. Ingbar is instructor in medicine, Harvard Medical School, Boston. Second honorable mention was given to the essay by Dr. Jacob Robbins, New York, entitled "Identification of Thyroglobulin in Human Serum After Large Doses of I^{131}." Dr. Robbins is research fellow at the Sloan-Kettering Institute, clinical assistant in medicine at Memorial Center for Cancer and Allied Diseases, and instructor in medicine at Cornell University Medical College.

Science Writers Association.—The National Association of Science Writers, which was formed in 1934, announces establishment of headquarters at 353 Fourth Ave., New York 10, with Miss Harriet G. Trowbridge of *Popular Science Monthly* as administrative secretary. The association, which meets twice a year (during the annual meetings of the American Association for the Advancement of Science and the American Medical Association), helps to administer the annual Lasker awards of the Albert and Mary Lasker Foundation for outstanding writing on health and medicine. It assisted the American Heart Association in establishing the annual Howard W. Blakeslee memorial award, given each year to the person making the best contribution through a communication medium to public understanding of heart and blood vessel disease. The association is undertaking an expanded, long-range program to (1) encourage accurate, reliable, responsible and interesting science writing, (2) increase the number of science writers and the number of newspapers, magazines, news agencies, and radio and TV outlets employing them, (3) point out to editors that much science news is already among the highest readership news they can use, (4) point out to scientists that their cooperation with responsible newsgatherers is essential if the people are to understand the directions in which our civilization is going, (5) aid and advise scientific and technical groups, and (6) enlist support for science.

Dermatologists Meet in Chicago.—The American Academy of Dermatology and Syphilology will hold its annual meeting at the Palmer House, Chicago, Dec. 5-10, under the presidency of Dr. Michael H. Ebert, Chicago. Special courses will be given Saturday and Sunday on granulomatous dermatoses, nevi and neoplasms, mycology, x-ray and radium therapy, bacteriology and virology of the skin, research methods in dermatology, anatomy and embryology of the skin, and special problems in dermatohistopathology. Monday morning special lectures will be delivered on pigmentation in its various phases by Dr. Thomas B. Fitzpatrick and Dr. A. Bunsen Lerner, Portland, Ore. Monday afternoon there will be symposiums on (1) internal medical aspects of cutaneous disease, (2) physical and radiation therapy, and (3) mucous membrane lesions (to be continued Tuesday morning). A round-table panel on dermatitis of the hands will be conducted from 2 to 5 p. m. Dr. Walter Bauer, Jackson professor of clinical medicine, Harvard Medical School, Boston, will deliver a special lecture, "Some Facets of Medical Education," at 8:30 p. m. in the grand ballroom. Symposiums on Tuesday include: "Physiology and Chemistry of the Skin," "Granulomas (Lupus Erythematosus)," "Industrial Dermatoses," "Bullous Dermatoses" (with a panel on the treatment of pemphigus), and "Dermatological Parasitology." Tuesday morning a round-table panel on medical writing will be held in private dining room No. 18, Club Floor. The committee on military affairs will have a luncheon meeting in the secretary's suite at 12 noon. Tuesday afternoon there will be a panel on the diagnosis and treatment of cutaneous malignancy in the grand ballroom and a round-table panel on techniques in the application of x-ray and radium in private dining rooms no. 15 and 16, Club Floor. Dr. Harry Goldblatt, director of laboratories and research, Mount Sinai Hospital, Cleveland, will deliver a special lecture, "The Experimental Induction of Malignancy," in the grand ballroom at 8:30 p. m. Wednesday symposiums include: "Syphilis," "History of Dermatology" (to be followed by round-table discussion on the influence of the British School of Dermatology on American and world dermatology), "Miscellaneous Dermatoses," "Surgical Management of Dermatologic Lesions," and "Cutaneous Allergy," which will include a panel on cosmetics in which Veronica L. Conley, M.N., Assistant Secretary, A. M. A. Committee on Cosmetics, will present "The Functions and Views of the Committee on Cosmetics of the American Medical Association."

FOREIGN

Institute for Research on Infertility.—The Municipal Hospital Hadassah in Tel-Aviv, Israel, has established an institute for research and treatment of infertility as a subunit of the gynecologic and obstetric department.

Dr. Carrell Honored.—Dr. Russell C. Carrell, medical director, Lago Oil and Transport Co., Ltd., San Nicholas, Aruba, N.W.I, was recently honored by Queen Juliana of the Netherlands, who appointed him Officer in the Order of Orange Nassau in recognition of his work toward improvement of the health of the Aruban population.

Society News.—The second annual meeting of the Persian Gulf Medical Society will be held at Dhahran, Saudi Arabia, Dec. 2-3 under the chairmanship of Dr. Neal J. Conan Jr., head, department of internal medicine, Arabian American Oil Company, Dhahran. Diseases endemic to the Persian gulf area will be discussed.

Cruise Congress in the Adriatic.—The International Congress of Hydrotherapy and Thalassotherapy, May 8-16, 1954, will be held on a ship that will travel up the Adriatic coast. The congress will have its headquarters in Dubrovnik, Yugoslavia. Among the topics to be considered are bioclimatic factors in thalassotherapy; significance of thalassotherapy in modern treatment of osteoarticular tuberculosis, significance of hydroclimatic treatment in rheumatic diseases, in diseases of the *respiratory tract, and hypertensive diseases,* and analytical methods in the examination of mineral waters. Persons wishing to participate in the congress should register before Dec. 31. The fee is $10. Further information may be obtained from Prof. Čedomil Plavšic, Beograd, Yugoslavia, Zeleni venac 1.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1953 Clinical Meeting, St. Louis, Dec 1-4.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Federation for Clinical Research, Eastern Section, Amphitheater, Children's Medical Center, Boston, Jan. 4. Dr. Walter Judson, Evans Memorial Hospital, Boston, Chairman.

American Laryngological, Rhinological and Otological Society:

Eastern Section, Waldorf-Astoria, New York, Jan. 8. Dr. Francis W. Davison, Danville, Pa., Chairman.

Middle Section, Park Plaza Hotel, St. Louis, Jan. 18. Dr. Ralph J. McQuiston, 20 North Meridian St., Indianapolis 4, Chairman.

Southern Section, Brown Hotel, Louisville, Ky., Jan. 16: Dr. Lester A. Brown, 490 Peachtree St., N.E., Atlanta 3, Ga., Chairman.

American Society for Surgery of the Hand, Palmer House, *Chicago,* Jan. 22. Dr. George V. Webster, 960 East Green St., Pasadena 1, Calif., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., *Syracuse* 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

Eastern Pennsylvania, Philadelphia, Jan. 15. Dr. Thomas M. McMillan, 330 S. Ninth St., Philadelphia 7, Governor.

Michigan, H. H. Rackham Auditorium, Ann Arbor, Dec. 5. Dr. H. Marvin Pollard, 1313 East *Ann St.,* Ann Arbor, Governor.

North Carolina, Chapel Hill, Dec. 3. Dr. Elbert L. Persons, Duke Hospital, Durham, Governor.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Western Surgical Association, The Drake, Chicago, Dec. 3-5. Dr. Michael Mason, 154 *East Erie St., Chicago 11, Secretary.*

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. Macrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General *Secretary.*

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretatiat, Escuela *de Tisiologia, Ciudad* Universitaria, Madrid, Spain.

Congress of International Association for the Prevention of *Blindness,* New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, *Switzerland, Secretary-*General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, *General Secretary.*

French Medical Congress of French Speaking Countries in the Caribbean, Port-au-Prince, Haiti, Dec. 15-21. For information write: Dr. Constant Pierre-Louis, School of Medicine, Port-au-Prince, Haiti.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, *Switzerland, July 15-19, 1954.* Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress on Child Psychiatry, University of Toronto, Toronto, Ontario, Canada, Aug. 13-14, 1954. Miss Helen Speyer, International Association for Child Psychiatry, 1790 Broadway, New York 19, New York, U. S. A., Executive Officer.

International Congress of Clinical Pathology, Washington, D. C., *U. S. A.,* Sept. 6-10, 1954. Dr. Robert A Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Diseases of the Chest, Barcelona, *Spain,* Oct. 4-8, 1954 Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, Executive Secretary.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6^e, France, Secretary.

International Congress of the History of Medicine, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: *Segreteria XIV* Congresso Internazionale di Storia della Medicina, Instituto di Storia della Medicine, Citta Universitaria, Rome, Italy.

International Congress of Hydroclimatism and Thalassotherapy, Dubrovnik, Yugoslavia, May 8-16, 1954. Prof. C. Plavsic, Zeleni venac 1, Belgrade, Yugoslavia, Secretary General.

International Congress of Industrial Medicine, Naples, Italy, *Sept.* 13-19, 1954. Professor Scipione Caccuri, Director, Institute of Industrial Medicine Policlinico, Naples, Italy, Chairman, Organizing Committee.

International Congress of Internal Medicine, Stockholm, Sweden, *Sept.* 15-18, 1954. Professor Anders Kristenson, Karolinska Sjukhuset, Stockholm 60, *Sweden, Secretary-General.*

International Congress of International College of Surgeons, Sao *Paulo, Brazil,* April 26-May 2, 1954. Dr. Max Thorek, 1516 Lake *Shore* Drive, Chicago. Illinois, U. S. A., Secretary-General.

International Congress on Mental Health, University of Toronto, Toronto, Ontario, Canada, Aug. 14-21, 1954. For information write: Executive Officer, International Congress on Mental Health, 111 St. George St., Toronto, Ontario, Canada.

International Congress *of Nutrition,* Amsterdam, Netherlands, Sept. *14-18, 1954.* For information write: Dr. M. van Eekelen, Centraal Instituut voor Voedingsonderzoek T.N.O., 61 Catharynesingel, Utrecht, *Netherlands.*

International Congress on Obstetrics and Gynecology, *Geneva, Switzerland,* July 26-31, 1954. Dr H. de Watteville, Maternité Hôpital Cantonal, Geneva, Switzerland, *President.*

International Congress of Ophthalmology, University of Montreal and McGill University, Montreal, Canada, Sept. 10-11, 1954, and Waldorf-Astoria, New York, N. Y., U. S. A., Sept. 12-17, 1954. Dr. William L. Benedict, 100 First Avenue Building, Rochester, Minnesota, U. S. A., Secretary-General.

International Congress of Orthopedic Surgery and Traumatology, Berne, Switzerland, Aug. 30-Sept. 3, 1954. *For information write:* Professor M. Dubois, Isle-Hospital, Berne, Switzerland.

International Congress of *Psychology,* Montreal, Canada, June 7-12, 1954. For information write: Prof. H. S. Langfeld, International Union of Scientific Psychology, Eno Hall, Princeton University, Princeton, N. J., *U. S. A.*

International Congress for Psychotherapy, Zurich, Switzerland, July 21-24, 1954. Dr. H. K. Fierz, Theaterstrasse 12, Zurich 1, Switzerland, Secretary General.

International Gerontological Congress, London and Oxford, England, July 12-22, 1954. Prof. R. E. Tunbridge, General Infirmary, Department of Medicine, The University, Leeds, England, President.

International Poliomyelitis Congress, Rome, Italy, Sept. 6-10, 1954. Mr. Stanley E. Henwood, 120 Broadway, New York 5, N. Y., U. S. A., Executive Secretary.

International Society of Blood Transfusion, Paris, France, Sept. 12-19, 1954. For information write: Colonel Julliard, Societe Internationale de Transfusion Sanguine, 53 Boulevard Diderot, Paris 12^e, France.

International Society for Cell Biology, Leiden, Netherlands, Sept. 2-9, 1954. Professor Peter J. Gaillard, University of Leiden, Leiden, Netherlands, Secretary.

International Society of Geographical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Professor Fred C. Roulet, Hebelstrasse 24, Basle, Switzerland, Secretary-General.

Journees Medicales, Paris, France, April 21-25, 1954. For information write: Secretariat of the Journees, 12, rue Pierre-Geofroix, Colombes (Seine) France.

Latin American Congress of Otorhinolaryngology, Caracas, Venezuela, Feb. 21-25, 1954. Dr. Victorino Marquez Reveron, Centro, Medico, Caracas, Venezuela, Secretary-General.

Latin American Congress of Physical Medicine, Medellin, Columbia, South America, Feb. 15-20, 1954. Dr. Cassius Lopez de Victoria, 176 East 71st St., New York 21, N. Y., U. S. A., Executive Director.

Pan American Congress of Otorhinolaryngology and Bronchoesophagology, Mexico, D.F., Mexico, Feb. 28-March 4, 1954. Dr. Pedro Hernandez Gonzalo, 8 No. 358, Vedado, Havana, Cuba, General Secretary.

Pan American Medical Association, International Medical Cruise Congress, S. S. Nieuw Amsterdam, Jan. 6-22, 1954. Dr. Joseph J. Eller, 745 Fifth Avenue, New York 22, N. Y., U. S. A., Executive Director.

Pan-Pacific Surgical Congress, Honolulu, Hawaii, Oct. 7-18, 1954. Dr. F. J. Pinkerton, Suite 7, Young Bldg., Honolulu 13, Hawaii, Director General.

Persian Gulf Medical Society, Dhahran, Saudi Arabia, Dec. 7-8. Dr. N. J. Conan Jr., Department of Internal Medicine, Arabian American Oil Company, Dhahran, Saudi Arabia, Secretary.

Sectional Meeting, American College of Surgeons, London, England, May 17-19, 1954. Dr. Michael L. Mason, 40 East Erie St., Chicago 11, Ill., U. S. A., Secretary.

South American Congress of Angiology, Sao Paulo, Brazil, July 1954. For information write: Dr. Rubens Carlos Mayall, Rua Senador Vergueiro 73, Rio de Janeiro, Brazil, S. A.

World Congress of Cardiology, Washington, D. C., and Bethesda, Md., U. S. A., Sept. 12-17, 1954. Dr. L. W. Gorham, 44 East 23d St., New York 10, N. Y., U. S. A., Secretary-General.

World Congress of International Society for the Welfare of Cripples, The Hague, Netherlands, Sept. 13-17, 1954. For information write: D. C. Schaap, Centrale Vereniging, Apeldoorschweg 51, Arnhem, Netherlands.

World Federation of Occupational Therapists, Edinburgh, Scotland, August 17, 1954.

World Medical Association, Rome, Italy, Sept. 26-Oct. 2, 1954. Dr. Louis H. Bauer, 345 East 46th St., New York 17, N. Y., U. S. A., Secretary-General.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 22-24, 1954. Sec., Dr. D. G. Gill, 537 Dexter Ave., Montgomery.

Colorado:* *Examination.* Denver, Dec. 15-16. Final date for filing application was Nov. 14. *Endorsement.* Denver, Jan. 12. Final date for filing application is Dec. 12. Executive Secretary, Miss Beulah H. Hudgens, 831 Republic Bldg., Denver 2.

Delaware: Dover, Jan. 12-14, 1954. Sec., Dr. Joseph S. McDaniel, 229 South State St., Dover.

District of Columbia:* *Reciprocity.* Washington, Dec. 14. Sec., Dr. Daniel L. Seckinger, 1740 Massachusetts Ave., N.W., Washington.

Guam: The Commission on Licensure will meet whenever a candidate appears or submits his credentials. Director of Medical Services, Guam Memorial Hospital, Agana.

Hawaii: Honolulu, Jan. 11-14. *Examination.* Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Idaho: Boise, Jan. 11-13, 1954. Executive Secretary, Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Illinois: *Examination and Reciprocity.* Chicago, Jan. 26-28. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 16-18. Exec. Sec., Miss Ruth V. Kirk, 538 K of P Bldg., Indianapolis.

Massachusetts: *Examination.* Boston, Jan. 12-15. Sec., Dr. Robert C. Cochrane, Room 37, State House, Boston 33.

Michigan:* *Examination.* Detroit and Ann Arbor, June 1954. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing 8.

Mississippi: *Reciprocity.* Jackson, December. Assistant Secretary, Dr. R. Whitfield, Old Capitol, Jackson 113.

Montana: *Reciprocity.* Helena, April 5. *Examination.* Helena, April 6-7. Sec., Dr. S. A. Cooney, 214 Power Block, Helena.

Nebraska:* *Examination.* Omaha, June 1954. Director, Mr. Husted K. Watson, 1009 State Capitol Bldg., Lincoln.

Nevada:* *Examination and Reciprocity.* Reno, Jan. 6. Sec., Dr. George H. Ross, 112 Curry St., Carson City.

New Hampshire: *Examination and Reciprocity.* Concord, March 10. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Mexico:* *Examination and Reciprocity.* Santa Fe, April 12-13. Sec., Dr. R. C. Derbyshire, 227 E. Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, Syracuse and New York City, Feb. 16-19. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

North Carolina: *Reciprocity.* Winston-Salem, Jan. 18. Sec., Dr. Joseph J. Combs, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 6-9, 1954. *Reciprocity.* Grand Forks, Jan. 9. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma:* *Examination.* Oklahoma City, June 9-10. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon:* *Examination.* Portland, Jan. 4-5. *Reciprocity.* Portland, Jan. 14-16. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia, January 1954. Acting Secretary, Mrs. Margaret G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Jan. 7-8. Admin. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Dakota:* *Examination.* Sioux Falls, Jan. 19-20, 1954. Reciprocity can be obtained at any time between meetings of board. Executive Secretary, Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:* *Examination.* Memphis, Dec. 16-17. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Vermont: *Examination.* Burlington, Feb. 1954. Sec., Dr. F. J. Lawliss, Richford.

Washington:* *Examination.* Seattle, Jan. 10-13. *Reciprocity.* Seattle, Jan 10. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

West Virginia: *Examination and Reciprocity.* Charleston, Jan. 11-13 Sec., Dr. N. H. Dyer, State Office Bldg., Charleston 5.

Wisconsin:* *Examination and Reciprocity.* Madison, Jan. 12-14, 1954. Sec., Dr. A. G. Koehler, 46 Washington Blvd., Oshkosh.

Wyoming: *Oral Examination and Reciprocity.* Cheyenne, Feb. 1. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Alaska: On application. Juneau or other towns in Territory as decided by Board. *Reciprocity.* On application. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

Arizona: *Examination.* Tucson, Dec. 15. Sec., Mr. H. D. Rhodes, University of Arizona, Tucson.

Connecticut: *Examination.* New Haven, Feb. 13. Address: State Board of Healing Arts, 52 Whitney Ave., New Haven 10.

Iowa: *Examination.* Des Moines, Jan. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Detroit and Ann Arbor, Feb. 12-13. Sec., Mrs. Anne Baker, 410 W. Allegan St., Lansing 15.

Minnesota: *Examination.* Minneapolis, Jan. 5-6. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Minneapolis 14.

Nevada: *Examination.* Reno, Jan. 5. Sec., Dr. Donald G. Cooney, Box 9005, University of Nevada, Reno.

New Mexico: *Examination.* Santa Fe, Jan. 17. Sec., Miss Marguerite K. Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, April 16-17. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, March 6, June 5, Sept. 11 and Dec. 4. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

Tennessee: *Examination.* Memphis, Dec. 30-31. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

Texas: *Examination.* April 1954. Location determined by number of applicants from different sections of the state. Sec., Brother Raphael Wilson, C.S.C., 407 Perry-Brooke Bldg., Austin.

Washington: *Examination.* Seattle, Jan. 6-7. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

Wisconsin: *Examination.* Madison, April 3. Final date for filing application is March 26. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

---

*Basic Science Certificate required.

DEATHS

Halford, Francis John ⊕ Honolulu, Hawaii; born in Cherokee, Iowa, Feb. 11, 1902; University of Pennsylvania School of Medicine, Philadelphia, 1926; in 1950 first vice-president of the Pan Pacific Surgical Association; member of the House of Delegates of the American Medical Association in 1946 and in 1948; past president of the Honolulu County Medical Society; chief of National Board of Medical Examiners for the Territory of Hawaii; president of the library board of governors, Honolulu County Medical Library 1947-1948 and in 1950; formerly secretary of the Hawaii Territorial Medical Association; member of the American Association for the Study of Trauma, Industrial Medical Association, American Public Health Association, American Society for the Study of Sterility, and the Honolulu Surgical Society; fellow of the American College of Surgeons; medical director of the Kamehameha Schools for Boys and Girls, 1929-1949; on the visiting staff, Queen's Hospital; on the courtesy staff, Kapiolani Maternity and Gynecological Hospital, Kauikeolani Children's Hospital, and St. Francis Hospital; died in San Francisco Oct. 1, aged 51, of heart disease.

Overton, Frank ⊕ East Patchogue, N. Y.; born in Bellport, N. Y., Dec. 29, 1867; College of Physicians and Surgeons, medical department of Columbia University, New York, 1893; past president of the Suffolk County Medical Society, of which he was secretary from 1902 to 1925; past president of the Associated Physicians of Long Island and the New York State Health Officers Association; served during World War I; for many years health officer of the town of Brookhaven and the village of Patchogue; district state health officer for Long Island from 1914 to 1923; formerly editor of the *New Jersey State Journal of Medicine, New York State Journal of Medicine,* and the *Long Island Medical Journal;* joint author of "Health Officer"; in 1917 received the degree of doctor of public health from New York University and in 1919 an honorary degree of doctor of science, Lafayette College, Easton, Pa.; clerk of the Patchogue Congregational Church and wrote a history of the church that was published a few years ago; died in the Pilgrim State Hospital in Brentwood Oct. 10, aged 85, of arteriosclerosis.

Crosby, Edward Harding ⊕ Hartford, Conn.; born in Hartford, March 27, 1901; Yale University School of Medicine, New Haven, 1928; certified by the National Board of Medical Examiners; specialist certified by the American Board of Orthopaedic Surgery; member of the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served during World War II; formerly a member of the board of the State Board of Examiners for Physiotherapy Technicians; orthopedic surgeon, J. J. McCook Memorial Hospital; member of the orthopedic staff, Hartford Dispensary; chief of orthopedic surgery, State of Connecticut Veterans' Home and Hospital, Rocky Hill; assistant in orthopedic surgery, St. Francis Hospital in Hartford and Newington (Conn.) Home and Hospital for Crippled Children; consultant, orthopedic staff, Litchfield County Hospital in Winsted; died Sept. 14, aged 52.

McLean, Isaac William, Charlotte, N. C.; born in Charlotte, N. C., Nov. 15, 1880; Baltimore Medical College, 1907; physician and surgeon of the Isthmian Canal Commission, Panama Canal Zone, from 1908 to 1912; surgeon in charge of the United Fruit Hospital in Panama from 1913 to 1918; served in the medical corps of the U. S. Army, 1918-1919, and from 1919 to 1943 was superintendent of the medical department, United Fruit Company Hospital, Kingston, Jamaica, British West Indies, where he was on the staff of St. Joseph Sanitarium and the Kingston General Hospital; died in Presbyterian Hospital Sept. 20, aged 72, of heart disease.

Brown, Alexander Gustavus Jr. ⊕ Richmond, Va.; born in Ashland, Va., Aug. 31, 1873; University College of Medicine, Richmond, 1898; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; formerly on the faculty of the Medical College of Virginia; past president of the Richmond Academy of Medicine; served on the staffs of the Medical College of Virginia, Hospital Division, and Stuart Circle Hospital, of which he was president; for many years editor of the *Virginia Medical Monthly;* died Sept. 16, aged 80, of cerebral hemorrhage.

Goldsmith, Norman Robin ⊕ Lancaster, Pa.; born in Pittsburgh June 15, 1907; University of Pennsylvania School of Medicine, Philadelphia, 1931; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology and the American Public Health Association; during World War II acting assistant surgeon in the dermatoses investigations section, U. S. Public Health Service; affiliated with St. Joseph's Hospital; author of a mystery novel; formerly associate editor of the *Pittsburgh Medical Bulletin;* died Oct. 8, aged 46, of multiple sclerosis.

Apking, Albert Carl, Chicago; Bennett Medical College, Chicago, 1912; charter member of the Garfield Park Community Hospital staff; died Oct. 24, aged 72.

Barr, Frank Ellis, Starkville, Miss.; University of Virginia Department of Medicine, Charlottesville, 1908; served during World War I; died Oct. 3, aged 68.

Beattie, Joseph Hoyt ⊕ Dobbs Ferry, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1902; served during World War I; member of the Association of Military Surgeons of the United States; affiliated with Dobbs Ferry Hospital, of which he was past president; died at sea aboard the liner Mauretania while en route to Europe Aug. 16, aged 73, of coronary thrombosis.

Blood, Hiram Isaac, Corning, Ark.; Eclectic Medical College, Cincinnati, 1914; died while on a train station platform Sept. 19, aged 74, as the result of a skull fracture received when he was hit by a mail sack tossed from a train.

Bosworth, Ralph Lyman, Corvallis, Ore.; University of Colorado School of Medicine, Denver, 1912; fellow of the American College of Surgeons; on the honorary staff of the Good Samaritan Hospital; died Sept. 14, aged 63, of cerebral hemorrhage.

Brody, Myer, Cleveland; Jefferson Medical College of Philadelphia, 1904; affiliated with Mount Sinai Hospital; died Sept. 5, aged 70, of coronary thrombosis.

Brown, Archie Lee ⊕ Salt Lake City; Jefferson Medical College of Philadelphia, 1908; for many years affiliated with Dr. W. H. Groves Latter-Day Saints Hospital; president and director of the State Savings and Loan Association of Salt Lake City; died Sept. 19, aged 69, of carcinoma of the colon.

Chapman, Walter Irving Jr. ⊕ Bayonne, N. J.; Cornell University Medical College, New York, 1934; specialist certified by the American Board of Surgery; served during World War II; affiliated with Jersey City Medical Center and St. Francis Hospital in Jersey City and Bayonne Hospital; died in the Baker Pavilion of New York Hospital Sept. 27, aged 43, of glioma.

Crabb, George Melville ⊕ Mason City, Iowa; Rush Medical College, Chicago, 1910; member of the House of Delegates of the American Medical Association in 1919; member of the Industrial Medical Association; fellow of the American College of Surgeons; past president of the Cerro Gordo County Medical Society; for many years member and president of the school board; affiliated with Park Hospital; a trustee of Grinnell (Iowa) College; died Sept. 16, aged 70.

⊕ Indicates Member of the American Medical Association.

Dale, Peter Hoffer ⊕ State College, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; member of the House of Delegates of the American Medical Association in 1946; an associate of the American College of Physicians; served in France during World War I; affiliated with Centre County Hospital in Bellefonte, where he died Aug. 15, aged 75, of coronary occlusion.

Davenport, Charles Albert ⊕ Newton, Mass.; Harvard Medical School, Boston, 1894; on the courtesy staff of Newton-Wellesley Hospital in Newton Lower Falls; died Sept. 28, aged 87, of myocardial degeneration.

Dotson, Charles Harvey, Danville, Ark.; Kansas City College of Medicine and Surgery, Kansas City, Mo., 1924; St. Louis College of Physicians and Surgeons, 1926; died in Arkansas Tuberculosis Sanatorium in State Sanatorium Sept. 23, aged 65, of tuberculosis.

Duden, William Robert, Palo Alto, Calif.; University of Rochester School of Medicine and Dentistry, Rochester, N. Y., 1939; formerly affiliated with the Palo Alto Hospital; died in Detroit, Mich., Sept. 23, aged 44, of congestive heart failure.

Gahagan, Wiley W. ⊕ Coushatta, La.; Memphis (Tenn.) Hospital Medical College, 1911; died Sept. 15, aged 72, of acute myelogenous leukemia.

Goldschmidt, Myer ⊕ New Britain, Conn.; Medical College of Virginia, Richmond, 1938; served as a battalion surgeon with the Third Army in Europe during World War II and was awarded the Bronze Star and five battle stars; affiliated with New Britain General Hospital and New Britain Memorial Hospital, where he was president of the staff from 1948 to 1950; died June 5, aged 42, of myocardial infarction.

Greenwalt, Kenneth E., Canton, Ohio; Ohio State University College of Medicine, Columbus, 1929; on the courtesy staff of Mercy Hospital; on the staff of the Aultman Hospital, where he died Sept. 24, aged 49, of astrocytoma of the brain.

Gunn, John William, Watervliet, Mich.; Louisville (Ky.) Medical College, 1894; died in Kalamazoo Oct. 2, aged 83.

Haynes, Charles Elmer ⊕ New York City; University of Oklahoma School of Medicine, Oklahoma City, 1915; affiliated with Woman's, Fordham, and St. John's hospitals and Union Hospital, where he died Sept. 28, aged 64, of coronary thrombosis.

Heichler, Joseph ⊕ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1913; died in the Bronx Hospital Sept. 12, aged 69, of heart disease.

Hemminger, John Ross ⊕. Somerset, Pa.; University College of Medicine, Richmond, 1901; past president of the Somerset County Medical Society; during World War II affiliated with Veterans Administration Hospital in Hines, Ill.; died Aug. 27, aged 77, of bronchopneumonia.

Herring, Harold Mandeville ⊕ Mount Vernon, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1912; specialist certified by the American Board of Physical Medicine and Rehabilitation; member of the American Society of Physical Medicine; affiliated with Lawrence Hospital in Bronxville, United Hospital, Port Chester, and Tarrytown (N. Y.) Hospital; died Oct. 8, aged 65, of coronary thrombosis.

Jonez, Hinton Denny ⊕ Tacoma, Wash.; University of Oregon Medical School, Portland, 1913; member of the American College of Allergists and the American Academy of General Practice; medical director of the multiple sclerosis clinic at St. Joseph Hospital; died Oct. 11, aged 63.

Jordan, Thomas Scott ⊕ Magnolia, Ark. (licensed in Arkansas in 1903); died in the Physicians and Surgeons Hospital, Shreveport, La., Sept. 24, aged 79, of pulmonary embolism.

Kenney, Joseph Raymond ⊕ Pittsburgh; Rush Medical College, Chicago, 1930; served during World War II; on the staff of the Westinghouse Electric Corporation; died in St. Joseph's Hospital Sept. 21, aged 56, of acute coronary occlusion.

Landauer, Seward L., Little Rock, Ark.; Rush Medical College, Chicago, 1901; died Oct. 3, aged 77, of concussion of the brain as the result of a fall.

Lilien, Adolph Abraham ⊕ New York City; Medizinische Fakultät der Universität, Vienna, Austria, 1917; affiliated with Mount Sinai Hospital; died Sept. 13, aged 65.

Malone, Franklin Jefferson ⊕ Clarksville, Tenn.; University of Tennessee College of Medicine, Memphis, 1923; served during World War I; member of the American Public Health Association; for 29 years with the Tennessee State Health Department as health director for Clarksville and Montgomery County; died Sept. 7, aged 61, of arteriosclerotic heart disease and auricular fibrillation.

Moloney, Bernard Aloysius ⊕ Upper Sandusky, Ohio; Starling Medical College, Columbus, 1907; died Oct. 6, aged 71.

Nelson, Kenneth Oliver, Chicago; University of Chicago School of Medicine, Chicago, 1947; served during World War II; resident in surgery at St. Luke's Hospital; died in the Evanston (Ill.) Hospital Oct. 24, aged 30.

O'Connell, John Patrick ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; for many years chief medical examiner of the Chicago Civil Service Commission; past president of the International Association of Police and Fire Surgeons and Medical Directors of Civil Service Commissions; died Oct. 20, aged 69, of acute myocardial infarction.

O'Hara, James Francis Jr. ⊕ Canton, Ohio; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1940; affiliated with Mercy Hospital; died in Cleveland Oct. 11, aged 38.

Painton, Henry McDonald, Rockville Centre, N. Y.; Long Island College Hospital, Brooklyn, 1923; served overseas during World War I and was awarded the Croix de Guerre; affiliated with Meadowbrook Hospital in Hempstead, South Nassau Hospital, and the Mercy Hospital, where he died Oct. 6, aged 55, of cerebral hemorrhage.

Patton, Benjamin Franklin, Terre Haute, Ind.; Physio-Medical College of Indiana, Indianapolis, 1903; died in St. Anthony Hospital Sept. 28, aged 86, of general arteriosclerosis and cerebral thrombosis.

Patton, James Elmer ⊕ Cambridge, Ohio; Starling Medical College, Columbus, 1903; died Oct. 7, aged 79, of cerebral hemorrhage.

Paulsen, Niels Peter ⊕ Logan, Utah; Rush Medical College, Chicago, 1907; formerly an officer in the regular U. S. Army; at one time on the staffs of the Good Samaritan and St. Vincent's hospitals in Portland, Ore.; affiliated with Latter Day Saints Hospital; died Oct. 9, aged 69, of carcinoma of the pancreas.

Pearlman, S. Joseph ⊕ Miami Beach, Fla.; Fordham University School of Medicine, New York, 1919; specialist certified by the American Board of Urology; member of the American Urological Association; served overseas during World War II and received the Bronze Star; on the staffs of the Mercy and Victoria hospitals in Miami and Mount Sinai Hospital; died in the Long Island College Hospital in Brooklyn Oct. 6, aged 57, of acute yellow atrophy of the liver.

Ramsey, Oscar Lee ⊕ Gretna, Va.; University College of Medicine, Richmond, 1905; in March, 1946, was proclaimed the outstanding citizen of Pittsylvania County by the Lions Club of Chatham; for many years president of the Peoples Bank of Gretna; died in the University of Virginia Hospital in Charlottesville Oct. 1, aged 79, of carcinoma of the bladder and uremia.

Redditt, George Irby ⊕ McCarley, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1889; died in Morgan City Oct. 1, aged 90.

Robinson, Schuyler C., Liberty, Tenn.; Chattanooga (Tenn.) Medical College, 1900; died in the Martha Gaston Hospital, Lebanon, Sept. 26, aged 78.

Sargent, William Henry, Oakland, Calif.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1905; specialist certified by the American Board of Radiology; member of the Radiological Society of North America, American College of Radiology, and the American Radium Society; affiliated with Samuel Merritt Hospital and Children's Hospital of the East Bay; died July 29, aged 71, of acute myocardial infarction.

Schmitz, Henry Charles ⊕ Des Moines, Iowa; Jefferson Medical College of Philadelphia, 1912; an associate on the staffs of Iowa Lutheran, Iowa Methodist, and Broadlawns General hospitals; on the staff of the Mercy Hospital, where he died Sept. 27, aged 70.

Schon, Edward ⊕ Lynn, Mass.; College of Physicians and Surgeons, Boston, 1912; for many years school physician; served on the board of trustees of the Lynn Public Library; died in the Lynn Hospital Oct. 1, aged 64.

Scott, Paul Newton ⊕ Lebanon, Ore.; University of Colorado School of Medicine, Denver, 1942; served during World War II; died Sept. 23, aged 38, of acute coronary occlusion.

Sheppard, Dempsey Orville ⊕ Barnesville, Ohio; Starling Medical College, Columbus, 1897; past president of the Belmont County Medical Society; served during World War I; affiliated with Barnesville Hospital, where he died Sept. 30, aged 86.

Snell, N. Russell ⊕ Chicago; Loyola University School of Medicine, Chicago, 1921; died in Hollywood, Fla., Oct. 22, aged 63.

Sours, Burton Osmond ⊕ Akron, Ohio; Ohio State University College of Medicine, Columbus, 1927; affiliated with People's Hospital, where he died Sept. 24, aged 60, of Alzheimer's disease and carcinoma of the rectum.

Sterrett, John Kennedy, Mount Vernon, N. Y.; Western Pennsylvania Medical College, Pittsburgh, 1891; died in the Mount Vernon Hospital Oct. 11, aged 84.

Stevens, George Michael ⊕ Los Angeles; Rush Medical College, Chicago, 1894; member of the American Public Health Association; formerly epidemiologist for the city health department; died in the Hollywood Presbyterian Hospital Sept. 22, aged 83, of abscess of right lung, pulmonary infarction, varicose veins, and ruptured appendix.

Storz, Christian, Toledo, Ohio; Detroit College of Medicine, 1891; died June 25, aged 89.

Swayne, Jap F. ⊕ Indianapolis; Indiana University School of Medicine, Indianapolis, 1913; served during World War I; died in the Passavant Memorial Hospital in Chicago Oct. 7, aged 66, of acute anterior myocardial infarction and coronary sclerosis.

Taber, Martin Emerald ⊕ Dallas, Texas; Marion-Sims College of Medicine, St. Louis, 1898; an Associate Fellow of the American Medical Association; specialist certified by the American Board of Otolaryngology; died Aug. 24, aged 78.

Taylor, Leland Harris ⊕ Oakland, Calif.; Harvard Medical School, Boston, 1923; served during World War II; affiliated with Peralta, Merritt, and Providence hospitals; died in the U. S. Naval Hospital Sept. 21, aged 60, of aspiration pneumonia and hypertensive cardiovascular disease.

Thomas, Harry V. ⊕ Chillicothe, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; member of the American Association of Railway Surgeons; past president of the staff of Proctor Hospital; died Sept. 19, aged 70, of coronary disease.

Thomas, William, Terrell, Texas; University of Nashville Medical Department, 1905; served during World War I; formerly vice-president of the Texas Neurological Society; for many years superintendent of the Rusk State Hospital and Terrell State Hospital; until 1950 superintendent of the Mexia State School in Mexia; died June 30, aged 71, of arthritis.

Tillman, William Gilbert ⊕ Easton, Pa.; Medico-Chirurgical College of Philadelphia, 1906; at one time vice-president of the Medical Society of the State of Pennsylvania; member of the emeritus staff and past president of the medical staff, Easton Hospital, where he died Sept. 11, aged 72, of cardiovascular disease.

Trigger, Harry W. ⊕ Bartonville, Ill.; Chicago College of Medicine and Surgery, 1913; member of the American Psychiatric Association; for many years affiliated with Peoria (Ill.) State Hospital; served on the staffs of St. Joseph's Hospital and Mennonite Hospital in Bloomington, where he died Oct. 10, aged 68, of cerebral thrombosis, arteriosclerosis, and hypertension.

Trimbo, Joseph Henry ⊕ Chelsea, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1904; also a graduate in pharmacy; died in Cedar Rapids, Aug. 18, aged 80.

Ulrich, Julius Hirsch, Peoria, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; also a graduate in pharmacy; served as examiner on the Selective Service Board during World War II until his retirement in 1944; for many years on the staff of the Proctor Hospital; died in the Methodist Hospital Sept. 15, aged 77.

Ungard, William Thomas ⊕ Xenia, Ohio; University of Cincinnati College of Medicine, 1927; past president of the Greene County Medical Society; affiliated with Greene Memorial Hospital, where he died Sept. 11, aged 56, of a heart attack.

Vannatta, George Woodruff ⊕ East Orange, N. J.; University and Bellevue Hospital Medical College, New York, 1913; fellow of the American College of Surgeons; member of the Industrial Medical Association; senior staff surgeon of Montclair Community Hospital, Montclair, where he was past president of the medical and surgical staff; died in Monmouth Memorial Hospital, Long Branch, Sept. 6, aged 65, of intracerebral vascular accident.

Van Winkle, Joseph Olin, Salem, Ore.; Willamette University Medical Department, Salem, 1905; served during World War I; for many years medical officer at the Klamath (Ore.) Indian reservation; at one time on the staff of the Oregon State Hospital; affiliated with Salem General Hospital, where he died Sept. 10, aged 77, of congestive cardiac failure, cardiovascular disease and arteriosclerosis.

Warfield, Mary Cabell ⊕ Tryon, N. C.; Woman's Medical College of Pennsylvania, Philadelphia, 1922; died in Mission Hospital, Asheville, Aug. 26, aged 58, of carcinoma of the uterus.

Waufle, Guy Clifford ⊕ Janesville, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; died in the Mercy Hospital June 18, aged 76, of left ventricular failure.

Webb, Rollin Edward ⊕ Lancaster, N. H.; Medico-Chirurgical College of Philadelphia, 1902; died Aug. 13, aged 77, of carcinomatosis.

Wegrocki, Adolph A., Newark, N. J.; Temple University School of Medicine, Philadelphia, 1927; formerly assemblyman from Essex County; assistant surgeon for the city fire department; on the staff of the Presbyterian Hospital; medical director of the Newark plant of the U. S. Steel Supply; died Sept. 27, aged 52, of carcinoma of the lung.

Westphal, Henry Gustave ⊕ Glendale, Calif.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1905; member of the American Academy of General Practice; fellow of the American College of Surgeons; affiliated with Physicians and Surgeons Hospital, Behrens Memorial Hospital, and Glendale Sanitarium and Hospital, where he died Sept. 2, aged 72, of hypertensive heart disease and diabetes mellitus.

White, Marvin Spears ⊕ Hamilton, Ala.; Louisville Medical College, 1903; served as county health officer; veteran of World War I; died Oct. 5, aged 74, of volvulus and bronchopneumonia.

GOVERNMENT SERVICES

ARMY

Influenza Vaccination.—American troops in certain overseas commands will be given anti-influenza vaccine this year, according to an announcement Oct. 26 by the Department of the Army. According to the Surgeon General, troops in Alaska, Europe, and the Far East will be given immunization during November. In addition, between Nov. 15 and March 31, troops designated as overseas replacements will be given influenza protection at ports of embarkation in the United States prior to sailing. The Surgeon General declared: "Experience during the 1952-1953 respiratory disease season, as in other years, demonstrated that effective use of influenza vaccine results only when it is administered prior to the onset of epidemics."

Medical Officers Receive Awards.—Three Army medical officers received awards Nov. 11, during the annual meeting of the Association of Military Surgeons of the United States. Col. Norman W. Elton, commanding officer, Chemical Corps Medical Laboratories, received the Louis Livingston Seaman prize for two papers, published in the *Military Surgeon,* entitled "Anticipated Progress of Sylvan Yellow Fever in Nicaragua: Plan for Attempt to Block Its Course in Honduras," and "Project to Block Progress of Jungle Yellow Fever in Northern Nicaragua and Its Calculated Risk of Failure." The Louis Livingston Seaman prize consists of an honorarium of $160 endowed in 1900 by the late Dr. Seaman, surgeon for the first U. S. volunteers during the Spanish-American War.

Major Wallis L. Craddock, Medical Corps Reserve, received the Welcome award for an essay entitled "An Evaluation of Pulmonary Features of Systemic Fungus Diseases," which will be published in the *Military Surgeon* in January, 1954. Major Craddock received the award from the trustees of the estate of Sir Henry Welcome, who founded the annual competition in 1916. Col. Douglas B. Kendrick, Surgeon, U. S. West Point Military Academy, along with Capt. Lloyd R. Newhouser (MC), U. S. Navy, chief of the professional division, Bureau of Medicine and Surgery, received the Gorgas award for research on blood and plasma substitutes during World War II. This award, in memory of Major Gen. William C. Gorgas, who was largely responsible for the elimination of yellow fever from the Canal Zone, consists of a medal, scroll, and an honorarium of $500.

NAVY

Courses for Naval Reserve Personnel.—Training courses of two weeks' duration for male Naval Reserve medical department personnel will be conducted during January, February, and March, 1954, as follows:

Insect and Rodent Control.—Classes are scheduled to convene at the Naval Air Station, Jacksonville, Fla., on the first and third Wednesday of each month. The 1st, 3rd, 4th, 5th, 6th, 8th, and 9th naval districts and the Potomac River Naval Command have been assigned quotas for this course.

Malariology and Insect Control.—Personnel of the 11th, 12th, and 13th naval districts are eligible to attend this course at the Naval Air Station, Alameda, Calif. Convening dates may be obtained from the commanding officer, Naval Air Station, Alameda.

These courses have been designed to familiarize reserve medical department personnel with the techniques and problems of these specialized fields of naval medicine. Eligible personnel desiring to attend in a pay status should submit their requests to the commandant of their home naval districts at the earliest practicable date. Participation in these courses will not increase the possibility of orders to extended active duty.

AIR FORCE

School of Aviation Graduates.—A class of medical officer was graduated Oct. 23 at the Air Force School of Aviatio Medicine, San Antonio, Texas. Brig. Gen. Edward J. Ker dricks, commandant of the school, awarded diplomas to th surgeons, including one British and one Canadian officer. Th graduation address was delivered by Col. Benjamin A. Strick land Jr., recently relieved as commander of the school's branc installation in Alabama to accept a new post at headquarter of the Twelfth Air Force in Europe. Although the class i cludes 37 officers who have had some World War II servic their average age is only 27. Though all have taken medica degrees and completed their internships, a dozen are just 2 years old. In the older group are 10 rated pilots, three forme navigators, and a bombardier, who gave up flying to stud flight medicine. Thirty of these graduates have received ove seas orders. The remaining USAF surgeons will be statione at Air Force medical units in this country for the present.

PUBLIC HEALTH SERVICE

New International Vaccination Certificate.—A new Interna tional Certificate of Vaccination has been issued by the Publi Health Service to replace the old International Certificate o Inoculation and Vaccination form. The old form is valid unti the expiration date of recorded vaccinations. When a travele applies for a passport the new certificate will be issued by th offices of clerks of the court and passport agencies of th Department of State in Boston, Chicago, New Orleans, Ne York, and San Francisco. The following principal change were made in the new form: 1. Smallpox and cholera vac cination certificates must bear the approved stamp called fo on the certificate. The signature of the certifying officer is n longer necessary, and signature alone is not acceptable. 2. Th smallpox certificate becomes valid immediately on revaccina tion. Primary vaccinations must be inspected and the result recorded. 3. The period of validity for the yellow feve vaccination certificate has been extended from four to si years. 4. The cholera certificate becomes valid beginning si days after the first injection or immediately in the case o revaccination. The new certificate may be purchased from the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C., at a cost of 5 cents per copy or $2.50 per 100.

Contracts to Abate Water Pollution.—During the second quarter of 1953, municipalities awarded contracts for 204 projects to abate water pollution and conserve water resources, according to the Public Health Service. The $64,600,000 represented by these public sewage treatment plant projects was more than double the amount for the contracts of the preceding quarter, and 55% greater than that reported in the corresponding 1952 period. Of the 204 projects, 118 are new plants, and 86 are additions, enlargements, or replacements.

Pointing out that 70 million people receive their drinking water from lakes and streams which are also used to carry away sewage and industrial wastes, Dr. Leonard A. Scheele, Surgeon General of the Public Health Service, said, "The safeguarding of our water resources is an important factor in the protection of health. The solution of this basic problem is the responsibility of the cities and industries of the Nation, and while progress being made through their efforts and those of the State water pollution control agencies is encouraging, it has not yet reached the level necessary to meet the growing needs."

FOREIGN LETTERS

BRAZIL

Amino Acids and Malaria.—In a paper published in *Anais Paulistas de Medicina e Cirurgia* (66:95 [Aug.] 1953) Dr. Ernest Schroeder, who lived for many years in China, reported the following facts. 1. Many tropical observers have commented on the part food plays in the control of malaria (the mechanism of this control is not known). 2. The ancient Chinese treated malaria with hydrolysed turtle shell and cow horn, which consist chiefly of amino acids, and thereby reduced the number of circulating plasmodia. 3. A mixture of tyrosine, beta-alanine, leucine, and cystine given by mouth caused clinical improvement in six patients with mild malariae malaria (nine weeks of administration in one case suppressed the infection; one patient became afebrile; and swollen spleens assumed normal size). 4. Injection of 50 mg. each of taurine and beta-alanine diminished the number of circulating parasites in 10 patients with malaria. 5. Beta-alanine in the pure form seemed effective in five patients (pantothemic acid was disappointing in one case tested, probably because its content in beta-alanine is low; carnosine, a derivative of beta-alanine given as meat extract, seems to act as a weak antimalarial). 6. Pure cystine in doses of from 100 to 200 mg. twice or three times daily elicited favorable responses in four patients (to taurine, an oxidation product of cystine, can be attributed a certain degree of suppressive value). These substances are an adjunct to the usual chemotherapeutic agents.

Gallbladder in Left Upper Quadrant.—A gallbladder located in the left upper quadrant of the abdomen in a patient without visceral inversion and proved by roentgenograms was described by Dr. Túlio Montenegro, of the University of Recife, in the *Revista Brasileira de Gastroenterologia* (4:839, 1952). He was able to find only 14 such cases in the literature.

Chagas' Disease in Childhood.—A paper published in the *Arquivo de Higiene e Saude Pública* stressed the seriousness of American trypanosomiasis (Chagas' disease) in children, which, far from being rare, is frequently found in rural zones infested by triatomes. The diagnosis of this disease without laboratory aid is very difficult. The authors obtained their data from an epidemiological survey of 2,210 children up to 10 years of age in 61 counties of São Paulo; 311 (14.7%) gave a serological reaction between 1+ and 4+. Because of the complexity of the test, Unti and his co-workers consider a 1+ or 2+ reaction as doubtful. Although only 21% of the 311 positive reactions in this study were in the frankly positive category, this survey should serve to call to the attention of the health authorities the importance of this disease in children.

Pancreatites and Leptospirosis.—Two cases of acute pancreatitis associated with leptospirosis icterohemorrhagiae were reported by Prof. João Alves Meira and Antonio Ulhoa Cintra and Drs. Aguiar Tartari, Bernardo Leo, Ricardo Veroneri, and Oswaldo Boehmer, of the university in a paper read before the department of medicine of the Associação Paulista de Medicina. The serum amylase and lipase levels in these patients were elevated. The serum agglutination for Leptospira icterohemorrhagiae was positive. The first patient, who presented radiological signs of acute pancreatitis, recovered but the other died. An autopsy confirmed the diagnosis. Areas of peripancreatic fat-tissue necrosis with an inflammatory infiltration where polymorphonuclear neutrophils predominated were found in the pancreas. The infiltration invaded the surrounding pancreatic tissue. The authors found only one report (five cases) of this complication in the literature.

ENGLAND

A Review of General Practice.—In 1950 the council of the British Medical Association appointed a special committee "to review the present position in general practice, its difficulties and its trends . . . and to make recommendations." The committee's report (*Brit. M. J.* [Sept. 26] 1953) is based on visits to 188 practitioners and a questionnaire completed by about 13,000 physicians. Of those visited, 93% "carried out some sort of examination in some cases," and 69% made whatever examination was necessary on all patients. Among 7% "there is a need for revision of the methods of diagnosis they use. . . . [they] do not seem to examine their patients except as a rarity." A surprising tendency to examine the abdomen through clothing and with the patient standing was noted. No examination couch was found in 11 surgeries. Over 90% of the practitioners seen were careful in the treatment of patients. Over 50% did little or no minor surgery. This proportion was much higher in the towns (73%) than in rural areas (40%). The reasons oftenest given for not doing minor surgery were lack of time and absence of a special fee.

Only 4% had found that the scope of their practices had benefited by changes in, or increased, cooperation by the public health service since the introduction of the National Health Service; 40% reported little or no contact with the service; and 41% said that their relations were satisfactory. As an example of what is described as "a deplorable lack of contact between the two branches of the profession," the case was cited of the medical officer of health of a large town who, in the middle of a widespread epidemic of influenza, issued a statement in the press that there was no epidemic in the city! Much criticism was heard of public health clinics and the medical officers working in them. Much criticism was also heard of public education on health matters; only 13% of the physicians thought that it might be beneficial.

Forty-five per cent applauded "the fact that their scope in practice has been widened by the introduction of the N. H. S. Not all of these applaud, or even like, the N. H. S. itself; but on one point they are clear—that they can do more for their patients." Although only 10% believed that a gap was being caused by the separate administrative arrangements under the National Health Service for general practitioners and consultants, many practitioners thought that consultants regard themselves as superior beings. It was often complained that "the younger consultant is on the defensive in order to conceal an inferiority complex . . . is interested in the scientific side and does not handle patients well." Twenty-three per cent said that all consultants should have experience in general practice as part of their training.

The view was expressed that "one of the potent causes of harm to the doctor-patient relationship is inadequate liaison between the hospital and the general practitioner." For instance, it is usually two or three weeks after the patient's discharge from the hospital before his physician receives a report from the hospital. A case was cited of a woman who, after a miscarriage, was discharged from the hospital the day after admission; the practitioner was not informed. Lack of knowledge of conditions in general practice is responsible for some of the trouble as in the case of a woman sent home 10 days after delivery and told to apply treatment to her baby's eyes every 15 minutes night and day! Lack of thought is another contributory factor as in the case of a young consultant who said that a patient's condition might be due to sleeping tablets prescribed by the general practitioner. "This patient and his family have now left the general practitioner and will probably influence other of his patients in the village to do the same."

Although most practitioners are agreed that the attitude toward them of at least some of their patients has deteriorated since the introduction of the National Health Service, no "proof of the current statement suggesting a wholesale dis-

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

appearance of friendly relations was found." The tendency, when it exists, is for the physician to be regarded as a supplier of medicines rather than a medical adviser and was reported by about half the practitioners, though by only a few patients. One physician was quoted as saying: "Some of the patients now merely include me with their errands: rations from the grocer, a call at the shoe repairer's, and a little cough mixture at the doctor's." The effect of the National Health Service on private practice is shown by the fact that four out of every five physicians reported that few, if any, of their private patients had remained with them as such. Of those interviewed, 43% did not want to have private patients, and 35% were anxious to preserve at least some private practice.

Ten per cent of physicians' premises were considered unsuitable, "rooms are dismal and bare, dirty and inhospitable, and often totally inadequate for the number of patients attending. One doctor sees patients in a porch." On the other hand, the physician is not always to blame; "one doctor has had to bolt his waiting-room chairs together to prevent their being taken." Over 90% of the physicians were found to have the full range of essential equipment.

Of those visited, 37% were more satisfied and 42% less satisfied since the introduction of the National Health Service. The percentage of those more satisfied is higher in the youngest age group and lower in the oldest. "This finding is hardly in keeping with the inference that might be drawn from the chorus of voices heard and the letters written on the subject." Practitioners preferred the National Health Service because they "can do more for their patients, can prescribe more freely, and can visit as necessary. Also there is no bother with bills now." Although the optimum number of patients per practitioner was considered to be 2,000 in country practice and 2,500 in town practice, 13% were quite happy with 4,000. Just under a third of the practitioners considered that they were subject to an excessive number of unreasonable demands on their services.

The committee tried to assess whether physicians were laying the blame for any shortcomings on the health service when, in fact, the cause was elsewhere. Although they "did expect to find the N. H. S. made into something of a whipping boy," this was the case in only about 14% of practitioners; on the other hand, "there is an undercurrent of feeling that the organization and administration of the N. H. S. proceed on their majestic way without due regard to the general practitioner or his patient. There is confusion, or there seems to be, regarding who should be blamed for the pin-pricks and the parsimony, for this is how many of them look at it. There is often criticism of their representatives. . . . I have heard more criticism of the profession's leaders than of those with whom they are negotiating."

The reading habits of physicians were as follows: 11% read several periodicals and medical textbooks; 70% regularly read one or two medical periodicals—usually a weekly and a monthly; and 18% read very little. On the whole the results of the postal survey were in agreement with those of the field survey. The committee concluded that (1) there has been at least some deterioration in the physician-patient relationship—more marked in industrial than in rural practice; (2) physicians, on the whole, are happier in their relationships now that fee-charging and the rendering of accounts are almost entirely a thing of the past; (3) where the physician is receiving payment for each patient by a per capita fee, as at present, the relationship is better than it would be in a salaried service; and (4) the institution of payment by salary would virtually deprive the patient of the free choice of a physician. After drawing attention to a discrepancy in the results of the field survey and the postal survey, the former showing that 35 and the latter that 66% of the physicians wanted a certain amount of private practice, the committee expressed the opinion that there is room for both National Health Service and private practice.

The committee believes "that general practitioners should undertake for N. H. S. patients those minor operations which, before the Service was introduced, they performed as part of clinical treatment in the ordinary course of general practice. The habitual transfer of minor surgery to the hospitals is neither necessary nor desirable. The training of the doctor has included instruction in this work, and . . . is part and parcel of general practice." Concern was also expressed at the diminishing amount of midwifery done by general practitioners. The committee believes "that midwifery is an integral part of general practice . . . and takes its stand with those who would allow any registered medical practitioner to provide a midwifery service for his patients if he wished and who would encourage him to increase his experience."

After pointing out that the survey has not revealed that health centers are essential to the improvement of the standard of general practice, the committee expressed the view that further experiment is desirable, including the development of health centers, in stages, from communal surgeries. The committee is in favor of group practice and considers that assistantship with a view to partnership is the best mode of entry into general practice.

In the opinion of the committee, general practitioner beds are "a desirable part of the doctor's equipment on both clinical and social grounds." These need not necessarily be in a separate hospital, but could be in a special ward allocated for the purpose in a general hospital. The committee agrees with the 81% of physicians who were in favor of some type of clinical assistantship for general practitioners. On the subject of overprescribing, the committee urges the profession to "exercise the greatest care in prescribing. . . . It should be realized by all that economical prescribing is usually good prescribing."

"The results of the surveys suggest that about half the general practitioners in the N. H. S. are reasonably happy and contented in their work, and that a similar proportion may be described as 'good' doctors." Most of the general practitioner's difficulties flow from "insufficiency of personal contact between [them] and practitioners in other branches of practice, and in the separation, in both practice and administration, of the three main branches of medicine—namely, general practice, hospital practice, and public health practice. . . . The practice of good medicine is also endangered when clinical activity has to be subordinated to administrative duties in the N. H. S. . . . The time and skill of the general practitioner are too often abused by patients who have no true need of his services or who regard him as only an intermediary to the hospital service. . . . Some of the effort which is given to public instruction in the wonders of scientific medicine and the marvels of the modern hospital service might with advantage be devoted to informing the public of the functions of the general practitioner and of the way in which his services should be sought. . . . At present there are more . . . financial advantages for the practitioner who is inclined to be superficial and who is easy with prescriptions but reluctant to sign on the chronic sick. There are too few openings and inducements for the careful, keen practitioner who likes to be thorough in his examinations and treatment and to have time for study and reflection."

FRANCE

Artificial Hibernation in Scarlet Fever.—Artificial hibernation is a new method of treatment for which the indications are being rapidly extended. On May 29 before the Medical Society of the Paris Hospitals V. de Lavergne and J. Schmitt reported a case of malignant scarlet fever treated with this method. Following the delivery of her second child, the patient contracted scarlet fever and had polypnea, delirium, a pulse of 145, and a temperature of 106.7 F. Artificial hibernation was tried. After the third day of this treatment, the patient's temperature was normal and hibernation was discontinued. During hibernation 2 million units of penicillin were given daily. On the fourth day the patient resumed consciousness; her behavior became normal; her temperature was 100 F and her pulse was 120. Three days later her temperature rose and bilateral pleurisy developed, which healed after repeated thoracentesis. According to the authors, artificial hibernation should be used in all patients with the malignant forms of scarlet fever, puerperal or pharyngeal, and probably all patients with hyperthermia, cardiac alterations, dyspnea, delirium, depression, and hemorrhages, whatever the cause.

Hibernation in Bronchopneumonia.—A frail 4-year-old child had measles, during which he developed whooping cough complicated by a severe bronchopneumonia associated with rapid respiration and cyanosis. His condition became hopeless, and F. Gomez and G. Gélin decided to use artificial hibernation. After intermittent venous perfusion using Laborit's classic "cocktail" in a dose of 0.5 cc. every 15 minutes, the child fell asleep, his respiratory rhythm stabilized, his cyanosis disappeared, and the oxygen inhalations, which had been given from the onset, could be decreased. After six hours, his temperature fell from 105.4 to 103.4 F. Ice bags were applied to his precordium, abdomen, and head. Antibiotics were given, and after 12 hours his temperature had fallen to 96.8 F and 500 cc. of the "cocktail" were again injected. After 24 hours the patient's temperature was 94.3 F and the oxygen inhalations were discontinued, but after 36 hours a relapse occurred, his temperature rose to 102.2 F, and cyanosis and tachycardia reappeared. Another "cocktail" was immediately administered and after four days the child was allowed to recover from the effects of the "cocktail." Convalescence was uneventful.

Hibernation in the Neurotoxic Condition of Nursing Infants.—On Nov. 25, 1952, R. Sorel, J. Rieunau-Serra, and H. Auban reported to the Toulouse Society for Medicine, Surgery, and Pharmacy on four patients with an extremely severe toxic condition. Classic treatment was ineffectual, these patients being children in a morbid and subcomatose condition with agitation and convulsions, severe dehydration, and cyanosis. The classical technique of hibernation was used. Three of the four children were cured. According to the authors, there are no contraindications to this treatment, but it necessitates continuous strict supervision. Appropriate antibiotic treatment should be given concurrently.

Acute Delirium Treated by Hibernation.—At the 51st Congress of French-speaking Psychiatrists and Neurologists, July 20 to 26, 1953, G. Berthier and J. Pougetoux reported a case of acute delirium cured, without sequelae, with artificial hibernation, and P. Picard, R. Lebras and P. Navarranne reported a case of severe carbon monoxide coma treated and cured with hibernation together with the encephalographic investigations pursued during the whole treatment.

Lead Poisoning.—At the Institute for Industrial Hygiene, Professor H. Desoille and Dr. C. Albaharry have resumed their study of experimental and human lead poisoning. According to them, this poisoning is much more frequent than is usually believed. It occurs under the form of various digestive disorders, spasmodic colitis, cholecystitis, cachexia, and even appendicitis, intestinal obstruction, or acute pancreatitis. Lead oxide is generally the etiological agent. The tin containing 80% lead that is used for galvanizing certain pipes is a source of danger. In a recent issue of *La Presse Médicale* (61:1247-1248 [Oct. 3] 1953), Prof. H. Desoille and Dr. Albaharry report a case of lead poisoning caused by a copper wire (used as the ground connection for a wireless set) surrounding a lead water pipe and thereby favoring electrolysis of the lead. Examination of the water from this pipe revealed the presence of 0.875 mg. of lead per liter. The patient's wife and daughter showed evidence of subclinical lead poisoning. The authors stressed the unequal sensitivity to the poison and the necessity of performing the three following tests to confirm a diagnosis of lead poisoning: search for stippling of the erythrocytes, coproporphyrinuria, and free protoporphyrin in the red blood corpuscles. They succeeded in discovering the exact cause of this patient's poisoning. Several tests of the water, performed after the copper ground wire was removed and also after a long period of stagnation of the water in the lead pipe, showed a level of 0.2 mg. of lead instead of 0.875 mg. per liter.

ITALY

Antituberculosis Vaccination.—Professor Salvioli, from the University of Bologna, discussed antituberculosis vaccination at a meeting of the medical and surgical society of the Romagna region May 10, 1953. In a brief historical review he said that Edoardo Maragliano used antituberculosis vaccination for prophylaxis and therapy as early as 1903. Maragliano's vaccine consisted of bacilli killed by heat, partially subjected to chemical disintegration, and enriched with the so-called integral poison. It was applied by scarification of the skin. The method by which it was applied was the weak point of the technique.

Several years later Calmette, who had been one of Maragliano's followers, and Guérin used a vaccine with attenuated bovine bacilli first on animals and then on men. For many years this vaccine was used orally on a large scale, especially in France. Later the percutaneous route by scarification and more recently the intradermal route were used.

Interest in prophylactic vaccination with dead bacilli was revived in 1926 following experiments by Petragnani and in 1933 when Salvioli used it on man. Petragnani's integral anatuberculin was used. A controversy arose, which is still in progress, between supporters of the vaccine consisting of attenuated living cultures and those who favored vaccination with dead cultures of bacteria that have not been deprived of their fundamental characteristics.

The supporters of Calmette's method assert that the vaccine obtained with dead bacilli induces only allergy in the organism, whereas that with living cultures not only produces allergy but prevents the onset of the infection as long as the germs of the vaccine remain alive.

The concept of a "premunition" was disproved by Salvioli in Paris in 1948. In his experiments a vaccine of the Calmette type with dead cultures yielded the same results as those obtained with Calmette's vaccine of living cultures.

In recent years some research workers have changed their opinion. In 1952 Dubrà, who had strongly supported Calmette's view, became a supporter of dead cultures vaccine. Recently the World Health Organization tuberculosis research office in Copenhagen reported that a vaccine consisting of one part of attenuated living cultures and 99 parts of dead cultures gave the same results as the best vaccine made of living cultures.

Professor Salvioli discussed vaccinal allergy. This persists in a very large percentage of cases (85 to 90%) beyond the 10th year when the dead culture vaccine is applied by the plurifocal intradermal route at the time of birth. In addition to a positive reaction to the tuberculin tests, there is also a high degree of resistance with this type of vaccination. This has been proved not only by experiments on dogs but also by numerous clinical observations. As an example he recalled the incident that occurred some years ago in the vicinity of Venice in which 14 children who had not been vaccinated against tuberculosis died of the disease while there was no death due to tuberculosis among an equal number of children of the same age in the same contagious environment who had been vaccinated.

Professor Salvioli pointed out the eutrophic effect of the vaccination and the greater resistance that vaccinated persons have even against nontuberculous diseases. This is analogous to what Weill and Werfeld had observed when the primary infection was overcome in a silent manner. He showed that the vaccination with vaccine of dead cultures of bacteria has as great a protective activity as the vaccination with Calmette's vaccine. He has been asserting since 1936 that the protection becomes manifest only after a vaccinal reaction. It is therefore necessary that a vaccinal focus be produced that will have a macroscopic and microscopic specificity and will have a complete evolution. For these reasons the doses of vaccine should be always adequate and the appropriate technique of vaccination should be followed. Scarification and tattooing are insufficient, and the vaccine should be introduced, in the proper dose, by the intradermal route.

The results obtained in Bologna on 12,000 children vaccinated at the time of birth are good. However, some pediatricians object to the necessity of making, even if simultaneously, four injections. On the other hand, the vaccinal disease caused by dead cultures vaccine differs in part from the true infection, in which there is a particular tropism of the tubercle bacilli toward the lymph nodes and the lymphatic tissue.

For these reasons Professor Salvioli has been using since 1950 a new vaccine (called Salvioli's diffusing vaccine) that consists of cultures killed by heat to which hyaluronidase has been added to give the dead cultures the migratory properties that are characteristic of living cultures. Experiments made at the Bologna pediatric clinic and a follow-up of more than 300 children vaccinated with Salvioli's diffusing vaccine gave interesting results. The studies are still in progress.

Professor Salvioli then discussed the multiple puncture vaccination that he has been using since 1938 in children with tuberculosis of the respiratory tract. He showed by means of radiograms taken by Professor Sighinolfi the good results obtained with this technique before the antibiotics became available. It is of undoubted efficacy if used properly and at the right time. Good results were obtained also in cases of osteoarticular tuberculosis and in the treatment of tuberculous meningitis when antibiotics were also used.

An animated discussion followed Professor Salvioli's report. Professor Costantini said that failure of the vaccination in skin positive persons is an indication that the allergy is not the expression of an infection but is only a particular phase during an incomplete process of immunization caused by a vaccinal focus.

Professor Lodi treated a group of infants with eczema by means of the Petragnani-Salvioli vaccine and obtained a cure in 82% of them. He observed that the sooner the vaccination was performed the greater the allergic manifestations were, thus confirming the conclusion that the Petragnani-Salvioli vaccine stimulates the allergic mechanism.

Professor D'Arcangelo spoke of the possibility of vaccine therapy with protein substances derived from cultures of tubercle bacilli. Professor Salvioli had mentioned it and had referred to it as a cellular stimulation of immunization in advanced stages of tuberculosis. He said that, in some patients in whom the tuberculous process has not been controlled by antibiosis or collapse therapy and in whom resistance to biochemotherapeutic agents has not developed, the evolution is definitely related to a negative state of immunization.

Professor Giugni compared the different characteristics of the Calmette and the Petragnani-Salvioli vaccines and said that the fact that the latter consists of dead human bacilli rather than of bovine cultures reassures the conscience of the physicians who perform the vaccination.

SWEDEN

Mass Radiography Surveys.—The mass radiography surveys that in recent years have been carried out in Sweden have demonstrated differences in the efficiency of antituberculosis work in various areas. A report published by Dr. E. Törnell on the mass radiography survey in Älvsborg County in a recent number of the quarterly journal of the Swedish National Association Against Tuberculosis shows how effective such a survey can be when the necessary measures for it are well organized. About 91% of the more than 250,000 persons over the age of 10 who were eligible for this survey were examined. About 60% of the new cases of tuberculosis discovered were found in persons between the ages of 30 and 59. About 20% were above this age, and another 20% were below it. The absentee rate was high among the elderly, and this was unfortunate in view of the prevalence of tuberculosis in old persons. About 83.6% of the persons who were found by this survey to be suffering from pulmonary tuberculosis were already on the registers of the tuberculosis dispensaries. This finding compares favorably with that of other counties, and most of the new patients had an early stage of the disease. The 401 new patients represented 0.15% of the persons examined. An important by-product of such mass surveys i the discovery of nontuberculous diseases, such as heart diseas and malignant disease, now sometimes amenable to operativ treatment. The 51 patients with malignant tumors and 75 wit benign tumors discovered represented 0.47 per 1,000 of th persons examined. Disease of the heart and blood vessels wa discovered in 585 persons, a rate of 2.16 per 1,000 person examined. The 96 patients with benign lymphogranulomatosi discovered represented 0.44 per 1,000 persons examined. Thi disease seems to be commoner in Älvsborg County than elsewhere in Sweden, and commoner in some areas than in othe parts of the county. This patchy distribution has also bee observed in the western part of the United States, where th disease has been found to be most prevalent. Dr. Törnel concluded that in spite of the trouble and costs entailed b such a survey, it serves a very useful purpose, but when ne cases of tuberculosis become still rarer it may be difficult t get the community to take a sufficiently active interest in thi measure.

Falling Infant Mortality.—More than a century ago Swede led the world in creating a professorship of pediatrics and i making the teaching of this subject compulsory in the medic schools. It was, therefore, natural enough for the subject o the Lennander lecture, delivered by Dr. Justus Ström in 195 to be "The Fall of the Infant Mortality in Sweden and th Causes Thereof." In this lecture, published with many diagrams in *Nordisk Medicin* for Sept. 17, Ström presents a imposing array of figures showing how well earned is th claim made by Sweden that its infant mortality is one of th lowest in the world. In the period 1911-1915, the infan mortality from whooping cough was 3.5 per 1,000, wherea in the period 1946-1950 it was down to 0.2. Between the sam two periods the infant mortality from measles fell from 1 t 0.02 per 1,000. This remarkable fall has been traced in pa to a decline in the virulence of both infecting organisms, bu though Ström admits that the two diseases run a milde course than they did 20 years ago, the decline in the mortalit from them should mainly be traced to the improved gener health of the community.

At present about 75% of the infant deaths occur in th first weeks of life, with congenital debility as the most important single cause. Here, there is room for improvemen particularly with regard to illegitimate infants. In Stockhol in the first half of the 19th century the mortality rate fo illegitimate infants was between 400 and 450 per 1,000, o about double that for infants born in wedlock. Since at tha time 41% of the live births in Stockholm were illegitimate the total infant mortality was appalling. Though there ha been a vast improvement since then, the investigations undertaken in 1948 by Thorën showed that the neonatal death from debility were 7.3% for the infants of the unmarried and only 3.3% for those of the married. He suggested tha attempts at criminal abortions might be partly responsible fo this difference because a medically plausible explanation fo premature births is found oftener among the married tha among the unmarried mothers. The relatively higher infan mortality in towns, as compared with rural areas, also suggests that criminal abortions are largely to blame in such cases.

One of Ström's diagrams deals with the competition between town and country over the reduction of infant mortality. Till the middle of the 1920's, the infant mortality was lower in the country, but since the turn of the century the social conditions and hygiene began to improve rapidly in the towns, with the result that they had overtaken and passed the country in the period 1936-1940. Since 1948 the towns have again lost their lead, and the infant mortality is now about the same for town and country. There has been a similar competition between different counties in the reduction of the infant mortality, with the lead being taken first by one and then by another county. Ström believes that the infant mortality can be still further reduced by means of modern drugs and antibiotics and by intensifying prenatal welfare, with special care devoted to the unmarried mother.

CORRESPONDENCE

ACUTE AND CHRONIC BACILLARY DYSENTERY

To the Editor:—Drs. Felsen and Wolarsky are to be congratulated for emphasizing the importance of bacillary dysentery. I should like to discuss three phases of their paper, acute bacillary dysentery, chronic bacillary dysentery, and their relationship to ulcerative colitis. The figures shown with respect to the increasing incidence of acute bacillary dysentery seem to be quite conclusive, but they do not conform to my recollections. One is on very dangerous grounds indeed to pit recollections against statistics, but many will recall that, in the earlier decades of this century, there were severe epidemics of bacillary dysentery in some areas and in other areas it was endemic. Certainly the infant death rate from bacillary dysentery in the first quarter of the century was high. It is exceedingly difficult for me to believe that the same condition obtains today or that the actual incidence of acute bacillary dysentery is as high in this third quarter of the 20th century as it was in the first quarter, or, indeed, in preceeding centuries. This is not meant to minimize at all the importance of bacillary dysentery, because it certainly remains, as Drs. Felsen and Wolarsky have properly pointed out, one of the great causes of morbidity today. It is an important disease that has not received adequate attention.

Chronic bacillary dysentery must be a rare disease for we have not been able to find it. Last month I had the privilege, however, of reviewing a fascinating paper in which Drs. Kositchek and Snell of California presented quite conclusive evidence of systemic and enteric infection, with multiple complications lasting over a period of several months, that was quite conclusively proved to have been due to Salmonella danysii. It may well be that there are more cases of chronic infection with Salmonella and other dysentery organisms than we have been able to find.

With respect to the relationship of these specific infections to chronic ulcerative colitis, it seems to me that again we do not know exactly what the situation is. Historically, in terms of each individual case, as Drs. Felsen and Wolarsky have pointed out, the onset of ulcerative colitis frequently simulates acute bacillary dysentery. Cultures are rarely made in this phase of the disease. It could well be that many of these patients have an initial bacillary dysentery. These authors in this and in previous presentations have brought before us very conclusive evidence that some of them do. Also in support of their view is the fact that a considerable number of patients with ulcerative colitis have a clear-cut history of Endomoeba histolytica infection at the beginning of illness with transition from acute amebic colitis to nonspecific colitis; hence, I am quite willing to accept the concept that, for a significant number of patients, acute bacillary dysentery is the primary inciting factor for chronic ulcerative colitis, and perhaps also for regional enteritis, and that the persisting inflammation and infection are due to other organisms. The main thesis of the paper, that more should be done to prevent acute and chronic bacillary dysentery, is certainly valid.

Walter L. Palmer, M.D.
University of Chicago
Department of Medicine
Chicago 37.

To the Editor:—Drs. Felsen and Wolarsky have presented an interesting and provocative paper on the problem of acute and chronic bacillary dysentery and have drawn attention to the possible relationship of these conditions to chronic ulcerative colitis. My clinical experience with chronic ulcerative colitis has been limited. I should, however, like to comment on the problem of bacillary dysentery itself.

The authors suggest that the increase in reported cases of acute bacillary dysentery represents a true rising incidence of this disease. I believe, on the contrary, that this increased morbidity is apparent rather than real and that it is due to the introduction of superior laboratory methods of diagnosis and to better reporting. Authorities in this field, such as Dr. A. V. Hardy and his associates, feel that in the absence of good morbidity data the best picture of the incidence of bacillary dysentery is given by the combined mortality figures for bacillary dysentery and nonspecified dysentery. The classic field studies of these investigators have shown that the majority of these latter cases are in fact bacillary dysentery. As shown in the table, the mortality rates from these conditions have shown a steady decline during the last 20 years and in 1950 actually amounted to less than one-fifth of the corresponding figures for 1936. While part of this decline is undoubtedly due to the recent development of more effective therapeutic measures, it is difficult for me to escape the conclusion that the incidence of bacillary dysentery has declined significantly during the last 20 years in the United States.

	Bacillary Dysentery		Nonspecified Dysentery		Combined	
Year	Deaths	Rate/ 100,000	Deaths	Rate/ 100,000	Deaths	Rate/ 100,000
1930	610	0.5	2521	2.1	3131	2.6
1935	725	0.6	1429	1.1	2154	1.7
1940	1027	0.8	1195	0.9	2222	1.7
1945	506	0.4	908	0.7	1414	1.1
1950	335	0.2	447	0.3	782	0.5

Data from "Vital Statistics of the United States" published by the U. S. Department of Commerce, Bureau of the Census, Washington, D. C.

Drs. Felsen and Wolarsky rightly stress the importance of detecting the healthy carrier of dysentery bacilli as one means of controlling the spread of the disease. In my experience it has been almost useless to attempt to isolate the causative organism from specimens shipped for any distance, even if a preservative has been added as suggested. Fresh specimens, preferably collected by the anal swab technique, must be plated out immediately in order to furnish a reasonable chance of isolating dysentery bacilli.

Drs. Felsen and Wolarsky make the categorical statement that chemoprophylaxis is of no value. I do not feel that there is any valid evidence on this point. While it is true that the sulfonamide compounds are of limited value in this respect because of the not infrequent occurrence of drug-fast strains, to my knowledge there have been no adequate trials of the newer broad spectrum antibiotics—chlortetracycline (aureomycin), chloramphenicol (Chloromycetin), and oxytetracycline (Terramycin)—as prophylactic agents under controlled conditions. These agents have given dramatic results in the treatment of the disease, and the development of drug-resistant strains has not been a problem as yet. They deserve prompt and adequate trials as possible prophylactic agents under controlled conditions. Only by such means can we determine whether chemoprophylaxis is a practical procedure or not.

BUREAU OF INVESTIGATION

THE BUSINESS OF BOLSTERING BOSOMS

Publicity concerning some surgical activities of Dr. Robert Alan Franklyn of Hollywood and New York has been the subject of a number of inquiries directed to the Bureau of Investigation of the American Medical Association. A magazine article in *Pageant* for August, 1953 (pages 68-75), wherein was described for the lay public generally a surgical procedure called "Breastplasty" (complete with before-during-and-after photographs) is the principal reason for such inquiries. A similar piece appeared as lead article in the *Southern General Practitioner of Medicine and Surgery* for April, 1953.

A white wrapper around each copy of *Pageant* invited attention in boldface type to "The Operation That Remolds Flat-Chested Women." The piece itself opened with the statement: "About 4,000,000 young American women suffer to some degree from micromastia . . . and another 10,000,000 from ptosis . . ." According to this article, Dr. Franklyn reported: ". . . In my own experience of many years as a plastic surgeon both in New York and Hollywood, I have found that at least one out of every three such women are psychologically affected, and that estimate may well be a conservative one." To continue:

"As a specialist, I began receiving so many referrals from other physicians of cases of this type that I investigated the possibility of curing micromastia and ptosis. I was able to devise a surgical technique known as Breastplasty, a relatively simple, 25-minute operation which overcomes the difficulties previously experienced in this field.

"At present, Breastplasty is available principally in Hollywood, although I also frequently operate in New York. The operation is within the budget of the average woman but, unfortunately, it is not a technique surgeons can learn out of a book. While I have had requests from many surgeons to observe the operation, there has been little opportunity for actual training in the technique."

As can well be imagined, this glowing invitation to pectoral pulchritude has caught the fancy of a good many who feel they are among the 4 million. A direct statement on this alleged number suffering from micromastia was made in the published article as though it were a well-established scientific fact, but nothing is offered to describe for the readers the identity of the poll-taker or the norms used in determining the extent of the alleged affliction. It is obvious that if certain motion picture stars in Hollywood were used as the standard, then the stated figure may well be woefully inadequate.

As for the erasure of this alleged defect from American women by means of a "relatively simple, 25-minute operation," one wonders how one operator is going to manage this single-handed. He can take care of only 7,280 if he works 10 hours a day, 7 days a week, for a solid year. One needs to extend the figures only one step further to see what frustration may face the overwhelming number of those left out.

Dr. Franklyn is further quoted in the *Pageant* article as having said:

"Finally, I would also like to offer a word of caution about two other forms of breast repair.

"For firming the breasts of young mothers, the standard technique used by many surgeons is to operate on the glandular structure itself in a series of multiple incisions. These circumscribe the nipple, then continue downward to the base of the breast and across it horizontally. Not only is the delicate glandular structure cut, but much visible scarring remains.

"For enlarging immature breasts, there is equally drastic surgery which involves a double operation. First, excess fat is removed from the region of the hips and then implanted in the breast. However, the transplanted fat will eventually become absorbed in the body tissue and the breast will relapse into its original state."

He offers instead:

"In Breastplasty, the drawbacks presented by these o two types of surgery are eliminated. In simplified steps, is how I proceed:

"1. Instead of cutting into the complicated part of breast, I make an incision of one and one-half inches in lower fold of the breast.

"2. I insert an inert soft plastic foam substance—actu a *nylon-like resilient material impregnated* with penicilli into the incision.

"3. I place this soft, foamed substance *behind* the bre over the pectoral or chest muscles. There it adds volu forcing the chest out, but it does not interfere with the c plicated glandular structure."

A plastic surgeon, in commenting on the third numbe representation, observes: "In the first place, he deposits mysterious material on the pectoral fascia; it does not co into contact with the pectoral muscle itself." Commenting the statement that this is "a relatively simple, 25-mir operation which overcomes the difficulties previously exp enced in this field," the surgeon continues:

"No operation can be predicted as to how long a time elapse between the incision, the operative procedure, and closing of the incision.

"Operative difficulties depending on many factors numerous and cannot be predicted."

The principal mystery, however, seems to be the ident of the substance used. In the report it is described as nylon-like resilient material impregnated with penicilli Inquiry to Dr. Franklyn discloses that "the substances u by me are not on the market—having been ordered s cifically from the supplier for test purposes."

It seems strange, indeed, that a material of such composit is offered to 4 million American women on the assura that it is harmless, efficient, and safe on a long-range ba Similar materials have been reported on by plastic surge who describe their animal work with polyvinyl sponge. Th report implies at least the prospect of a gristle-like devel ment in the implant which is apt not to be what most la would like to carry around with them. Grindlay and Waug *report in part:*

". . . Sponges of various size and shape were placed subcutaneous tissue in six dogs; in the same dogs a co shaped molded sponge was also placed under a bre nipple . . .

". . . Gradually the sponges became firm. The degree firmness which the sponge mass eventually had was appro mately that of a mass of fibrous tissue of the same sha and size.

"With the exception of certain experiments the implant sponges did not become fixed to surrounding tissue, ev though the sponge itself contained blood vessels and co nective tissue."

In a private communication, one of the authors (John Grindlay, M.D.) wrote the Bureau of Investigation in part follows:

". . . The conclusions reached in the paper which I Waugh and I prepared in 1951 and which appeared in t September issue of that year of the A. M. A. Archives Surgery, viz., that long-term experiments are necessary befo polyvinyl sponge can be given unqualified approval for clinic use and that one must appreciate that an implanted spon will become a piece of fibrous tissue and thus less resilie and firmer, still hold. . . ."

In another such communication, a copy of which was su mitted to the Bureau, Dr. Grindlay stated:

"It is true that one of the experiments I performed on do was to place sponge subcutaneously under a breast nippl The original purpose was to test it for such use in plast surgery. The firmness and rigidity which developed in th implanted mass seemed to me undesirable. . . .

"It may be there will be enough normal tissue covering th implanted sponge that one will not be greatly aware of th firmness, especially if not too massive an implant was use

---

1. Grindlay, J. H., and Waugh, J. M.: Plastic Sponge Which Acts as a Framework for Living Tissue, A. M. A. Arch. Surgery 63: 288-297 (Sept.) 1951.

Another reason for using caution in the matter of size would be the inability of the implant to change shape with changes in position of the body."

According to the biographic records, Robert Alan Franklyn is not shown as a member of his local medical society or of the American Medical Association. He is shown as having graduated from New York University College of Medicine in 1941. He was licensed to practice medicine in New York in 1942 and in California and New Jersey in 1943. He is not shown as a member of any specialty group or as a diplomate of any specialty board. There is indication, however, that he served residencies in anesthesiology and dermatology.

It is strange indeed that a physician would permit publication of the details of a surgical procedure in a popular magazine when such procedure does not appear to have the benefit of exhaustive tests on animals to establish its safety and efficacy.

Perhaps, however, it is no more strange than to find Dr. Franklyn listed under the heading "Physicians and Surgeons (M.D.)—Plastic Surgery" in the classified section of the Miami, Fla., telephone directory. The entry instructs readers to call the operator at Hollywood, Calif.

COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

The following analysis of regulations recently prepared and distributed by the Department of Defense concerning the new "Doctor-Draft" law has been made by the Council on National Emergency Medical Service. This résumé has been reviewed by the Office of the Secretary of Defense (Health and Medical) and verified as to its accuracy.

C. Joseph Stetler, *Secretary.*

ANALYSIS OF DOCTOR-DRAFT REGULATIONS

Administrative regulations issued by the Department of Defense to implement the revised version of the "Doctor-Draft" law were published Oct. 7, 1953. These regulations are intended to consolidate, reissue, and modify various earlier Department of Defense directives promulgated pursuant to Public Law 779, 81st Congress, as amended. The résumé will be confined primarily to the provisions of the directive that established new policy and those that substantially amend regulations previously in effect.

A. *The Executive Agent*

The Department of the Army is designated as the executive agent for the Department of Defense and is charged with the following administrative responsibilities in connection with the new "Doctor-Draft" law:

(1) determining the acceptability of special registrants for military service in accordance with established professional, physical and moral standards;

(2) maintaining appropriate liaison with the Selective Service System; and

(3) making departmental allocations of special registrants ordered for induction, following consultation with representatives of other military departments.

B. *Professional Standards*

A special registrant (medical) will be considered professionally acceptable if:

(1) he is a graduate of a medical school approved by the Council on Medical Education and Hospitals of the American Medical Association or is a graduate of a foreign medical school whose graduates are recommended for consideration by that council; or

(2) he is a graduate of any other medical school and possesses a degree of doctor of medicine as a result of completing a four year course of medical instructions; has had 12 months or more of intern or residency training approved by the Council on Medical Education and Hospitals or is a diplomate of an American Specialty Board; and is licensed to practice medicine in a state or territory of the United States or the District of Columbia or is a diplomate of the National Board of Examiners.

C. *Physical Standards*

All special registrants will be considered to be potentially acceptable for military service provided they can reasonably be expected to be productive in the armed forces. These physical standards are substantially the same as those adopted by the armed forces on Jan. 12, 1953.

D. *Moral Standards*

A special registrant will be found *not* acceptable for military service if he has:

(1) been convicted by a civil court of an offense where punishment exceeds one year, or of any offense punishable by death, or

(2) a record of difficulties with law enforcement agencies exhibiting criminal tendencies or other traits of character that would render him unfit, or

(3) previously been separated from the armed forces under other than honorable conditions or for the good of the service, or

(4) had criminal charges filed against him, alleging a violation of state or federal law, which are still pending.

The fact that special registrants are not commissionable or do not desire or will not accept a commission will *not* preclude them from induction or acceptance in the armed forces.

E. *Processing of Requirements*

The estimated military (uniformed) requirements will, after processing within the Office of the Secretary of Defense, be referred to the Assistant Secretary of Defense (Health and Medical) who will obtain the comments of the Health Resources Advisory Committee, Office of Defense Mobilization.

The Assistant Secretary of Defense (Health and Medical) will also coordinate the report with the Assistant Secretary of Defense (Manpower and Personnel) prior to referral to the Secretary of Defense for submission to the President. The Assistant Secretary of Defense (Manpower and Personnel) will place approved calls with the Selective Service System.

F. *Commissioning of Special Registrants*

Special registrants otherwise qualified may be commissioned under the following circumstances:

(1) upon receipt of an application from a special registrant ordered for induction and allocated to the branch of the armed forces to which the application is submitted;

(2) upon receipt of an application for appointment and immediate active duty (within 90 days) from a special registrant who is not under orders for induction as a special registrant;

(3) upon receipt of an application for appointment to fill a vacancy in the reserve from a priority 4 registrant with 21 months or more of prior service;

(4) upon receipt of an application for participation in a professional training program; and

(5) upon receipt of an application from special registrants who are also liable under the basic Selective Service Act, providing such registrants have, as regular registrants, been placed by their local boards in a class available for military service.

G. *Determination of Rank*

The rank assigned will be based upon the number of years spent in appropriate professional activities subsequent to graduation from medical school and prior to the time of entry on active duty. The following schedule will apply:

Physicians and Dentists

	Grade	
Years	Army and Air Force	Navy
Less than 4	1st Lieutenant	Lieutenant (j. g.)
4 or more but less than 11	Captain	Lieutenant
11 or more but less than 18	Major	Lieut. Commander
18 or more*	Lieut. Colonel	Commander

---

* Persons with 25 or more years of professional experience who have achieved national prominence as authorities in their particular specialty may be appointed in the grade of colonel in the Army or Air Force or as captains in the Navy.

H. *Readjustment of Grades*

Any physician appointed in a reserve component or now serving on active duty who would have been entitled to a higher grade if the subject directive or Public Law 84, 83rd Congress, had been in effect at the time of his current appointment, will be entitled to an adjustment of grade.

In the case of a reservist, he will, immediately prior to being ordered to active duty, be reappointed or promoted to such higher grade. A special registrant on active duty will, at the earliest practicable date, be reappointed or promoted to such higher grade.

Pursuant to the "Doctor-Draft" law, appointments to grades higher than major or lieutenant commander can be made without referral of the case to a board of officers convened by the secretary of the service concerned.

I. *Ordering Commissioned Personnel to Active Duty*

(1) Reserve medical personnel will, *insofar as practicable,* be ordered to duty in accordance with the priorities established in the "Doctor-Draft" law.

(2) Members assigned to organized reserve units will be called to active duty as individuals in accordance with their priority except when their units are brought into active duty.

(3) Physicians who are members of a national guard unit will not be called to active duty at this time (unless the unit is called), providing they were members of such a unit prior to June 25, 1950.

(4) The "essentiality" of medical reservists will be determined by the National Advisory Committee to the Selective Service System. Requests for delay on this basis may be made by a physician or an employer directly to the branch of the armed forces involved. An appeal may be submitted directly to the Secretary of Defense in the event that a request for such a delay is disapproved.

(5) Any physician qualified for a reserve commission is given an opportunity to volunteer for a period of active duty of *not less than 24 months.*

J. *Interservice Transfer*

Physicians holding reserve commissions in the armed services may apply for transfer to another service. An application containing specific identifying information must be submitted through command channels and must bear the endorsement of the parent and requested departments, irrespective of their approval or disapproval in each case.

MEDICAL MOTION PICTURES

The Frustrating Fours and the Fascinating Fives: Ages and Stages Series: 16 mm., black and white or color, sound, showing time 21 minutes. Produced in 1952 by Crawley Films Ltd., Ottawa, for the National Film Board of Canada. Procurable on purchase (color $175.00, black and white $95.00) from McGraw Hill Text Films, 330 West 42nd Street, New York 36. For rental, consult local film libraries.

With the emphasis on the normal child, the film deals with common incidents in the lives of 4-year-old and 5-year-old children and interprets them in the light of underlying behavior patterns and growth needs. The 4-year-old who knocks down his well-behaved younger cousin and calls his mother a "stinker" in front of the relatives, the bewildered 5-year-old confronted with his dead canary, and the children happily playing cowboy and shooting games, are only three among the many situations portrayed that will provide excellent discussion material. The nursery school and kindergarten scenes, with their comparison of the different kinds of behavior and direction needed at 4 and 5, should also be very helpful for parents and teachers. This film is recommended for the following groups: parents of young children, nursery and kindergarten teachers, pediatricians and pediatric nurses, and social work trainees in child care and child guidance programs. Since the film is self-explanatory and does not involve psychiatric concepts, it could be shown without discussion on the part of a professional consultant. The film is very good from a production standpoint.

BUSINESS PRACTICE

The following material is adapted from a public relations manual issued by the Public Relations Department of the American Medical Association.—Ed.

MORE ABOUT FEES

The best way to arrive at a fair scale of fees is to check with the county medical society and other physicians. Fees differ somewhat in various communities and in different parts of the country. Many medical societies have worked up informal, unpublicized average fee schedules that can serve as a guide to local physicians in setting their charges. Some societies are publicizing average fee schedules so that patients know about how much a physician should charge for such routine medical procedures as office, house, or hospital calls. These schedules serve as a yardstick by which to measure fees. The old philosophy of charging the wealthy more for their medical care in order to provide charity to the needy is fast fading. Any ethical physician will donate his care to those who are unable to pay if he knows the circumstances. Today most physicians have informal fee schedules of their own—sometimes existing only in their heads—based on their actual experience in the community. They charge a fee that can be lowered or cancelled under certain circumstances.

Though every doctor should charge enough to command respect, his fees should be reasonable and consistent with the average patient's ability to pay. A physician sells his time and his services, but he cannot set his fees on the basis of the time spent per patient. Nor can his fee for an intangible service be compared with the price of a piece of merchandise. Because every patient is different, medicine must be practiced on a personalized basis. Medical care has little value except to the patient himself—therefore, values of similar services differ. No one but the doctor himself is in a position to estimate the value of these services. Sometimes a patient may question a medical fee. Many physicians then say: "This seems to me to be a fair fee for your case, but you pay me what you think it is worth." Nearly every physician who uses this method reports that the patient will pay the original sum asked and sometimes will pay a little more.

Once he has established a fee, a physician should adjust charges only on a cost basis. According to a professional management official, 15% to 20% is a fair profit for a physician. Sometimes he can cut his fees on an efficiency basis. It is impossible to put bargain rates on good medical care, but every doctor can strive to give better medical service per dollar and should remember that he is never successful because of the price he places on his services—he is successful only because he is a good doctor doing a good job. Here, in brief, are tips on how to set fees fairly:

1. Check with the county medical society to learn what average fees are in the area.
2. Check with other physicians to learn what fees are charged.
3. Charge a reasonable fee that can be lowered or cancelled if circumstances warrant.
4. Charge enough to command respect.
5. Set fees consistent with the average patient's ability to pay.
6. Adjust fees on a cost basis only.
7. Do not put bargain rates on medical care; this tends to lower quality.
8. Give the best medical service possible per dollar.

MEDICAL LITERATURE ABSTRACTS

UNITED STATES

A.M.A. Am. J. Diseases Children, Chicago

86:265-394 (Sept.) 1953

Epidemiological Aspects of Gamma Globulin Prophylaxis in Poliomyelitis: Critical Evaluation. J. A. Bell.—p. 311.

Aerosol Trypsin in Bulbar Poliomyelitis.—Aerosol trypsin therapy was instituted in the treatment of a 6-year-old boy with bulbar poliomyelitis complicated by respiratory difficulty despite a tracheotomy. Accumulation of extremely tenacious mucus made it difficult to suction the tracheotomy tube and the trachea. The aerosol therapy was continued twice daily for seven days. Ten minutes before each aerosol trypsin administration, the patient was given 10 mg. of diphenhydramine (Benadryl) hydrochloride to prevent possible allergic reactions. Usually, the therapy was completed in about 10 to 15 minutes. There was general improvement in the patient following each such administration, with a pronounced increase in the fluidity of the aspirated secretions, making aspirations much easier and more effective. With the gradual improvement of the patient, aerosol trypsin therapy was given only once daily for four more days and then discontinued. Subsequently several respiratory infections occurred in the patient, and at one time segmental atelectasis was demonstrated by roentgen rays and by a definite decrease in tidal volume. Aerosol therapy was reinstituted and was given twice daily for four days. There was prompt improvement, with apparent clearing of the atelectasis.

Diagnostic Pneumoperitoneum in Sex-Endocrine Disturbances.—Transabdominal pneumoperitoneum was performed in 16 patients between the ages of 21 months and 23 years with sex-endocrine disturbances. Seven patients had ovarian agenesis, one primary hypopituitarism, two pituitary hypoovarianism, one cystic ovary, two constitutional sexual precocity, and three pseudohermaphroditism. The technique consisted of introducing 500 cc. of carbon dioxide into the peritoneal cavity and then visualizing roentgenographically the outlines of the pelvic viscera. No hazards were observed. Results showed that transabdominal pneumoperitoneum may aid in establishing the clinical diagnosis and thus avoid laparotomy in some sex-endocrine disturbances in which detailed physical examination as well as available laboratory studies may be diagnostically inconclusive. The method is of special value in the study of children with such disturbances because of the difficulty of adequate pelvic examination. Early diagnosis is desirable in order to plan future medical and/or surgical management. Recently the authors performed pneumoperitoneum on an 11-week-old infant with pseudohermaphroditism. Female pelvic structures were clearly demonstrated. No untoward reaction resulted from the procedure.

Radioactive Iodine in Treatment of Cancer of Thyroid.—As a result of their 10 years' experience with radioactive iodine in the treatment of cancer of the thyroid, the authors state that radioactive iodine should be used for treating cancer of the thyroid (1) in patients whose tumors cannot be removed by surgery and (2) in patients whose cancers are capable of concentrating cancerocidal doses of radioiodine without serious damage to extrathyroid tissues. The misuses of radioiodine in the treatment of cancer of the thyroid occur (1) when it is used for patients whose tumors could be removed by surgery, (2) when it is used for patients whose tumors concentrate so little of the isotope that a therapeutic effect is impossible, (3) when so little radioactive iodine is used that it destroys only the function without any therapeutic effect, and (4) when the radioactive iodine is administered in doses that are so great (single or cumulative) that serious body irradiation occurs. In the authors' clinic patients with metastatic carcinoma of the thyroid who are under consideration for treatment with radioactive iodine are first evaluated as to the capacity of their tumors to concentrate radioactive iodine by administration of tracer doses of the isotope. If the urinary excretion is less than 40% of the administered dose, the patient is considered a candidate for treatment, and a second, but larger, test dose of I^{131} is given, after which daily urinary

---

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

excretion is determined, in vivo measurements are made over the tumor at 48 hours, and the blood level is determined daily for at least seven days and plotted graphically. From the graphic plot of blood levels and the I^{131} retained in the body the amount of radiation that will be delivered to the hematopoietic system and other extrathyroidal tissues is calculated. From this calculation and the estimated size of the tumor the authors try to determine whether they can deliver a cancerocidal dose of I^{131} without doing the patient serious harm. Then a maximum but safe dose of radioactive iodine is administered. By following these rather rigid criteria in treating 35 patients with cancer of the thyroid, 10 patients obtained objective improvement, 10 showed transient objective improvement, 8 were therapeutic failures, and 7 were treated too recently for evaluation. The results obtained demonstrated that a large number of cancers of the thyroid can be made to assume certain functions of normal thyroid tissue, and certain cancers of the thyroid can be at least partially destroyed with radioactive iodine.

Toxoplasmosis.—In a study of families exposed to pet dogs infected with toxoplasmosis, Prior and co-workers found a 26-year-old woman with Toxoplasma parasitemia who appeared to be in excellent health and a 28-year-old woman with toxoplasmic encephalitis and neuroretinitis. The younger woman had been in close contact with the infected dog for four weeks. Leukocytosis and a Toxoplasma antibody titer of 1:160 revealed by the dye test were the only observed deviations from normal. The occurrence of T. parasitemia in this young woman substantiated the concept that there must be asymptomatic Toxoplasma infections in women of child-bearing age to serve as a source of the congenital toxoplasmosis. Although the authors did not have proof that the patient contracted T. parasitemia from the sick dog, the relationship of active toxoplasmosis in the dog and T. parasitemia in the young woman appears to be more than coincidence. Since tonsillitis, pneumonitis, and enteritis were observed in the dog at autopsy, dissemination of the Toxoplasma was possible through the sputum, saliva, and feces. Demonstration of acquired toxoplasmosis in the adult is uncommon. The infection in the young woman with encephalitis was considered to be acquired because of the acute symptoms of recent origin and the high Toxoplasma antibody titer revealed by the complement-fixation and dye test. Concurrently, her pet dog had toxoplasmosis of the digestive tract, making dissemination of organisms in the vomitus and feces a possible source of her infection. A third case of toxoplasmosis is reported in a 2-year-old girl having concurrent severe pertussis that "masked" the disease. The child died and necropsy revealed focal myocarditis with numerous intracellular Toxoplasma organisms. There was perivascular round cell infiltration in the brain, and Toxoplasma pseudocysts were observed in and around focal areas of necrosis and granulomatous inflammation. It was impossible to obtain the cooperation of the family for any correlative search for Toxoplasma infection in other members of the family or the household pets.

Prevention of Postoperative Thromboembolism.—In 2,700 consecutive surgical patients, the indications and contraindications for prophylactic administration of bishydroxycoumarin (Dicumarol) were established for the first 1,144 patients, 872 of whom were considered to be excellent surgical risks giving little reason to expect an intravascular thrombosis in the postoperative period, while 272 were given prophylactic anticoagulant therapy. There were 41 postoperative thromboembolic complications in 35 of the 872 untreated patients, an incidence of approximately 1 in every 25 patients, i. e., an incidence of 4% that is much higher than that reported in the literature. The incidence of pulmonary emboli in the 872 untreated patients was 1.6%, with a mortality rate of 0.34%. Among the 272 patients who received bishydroxycoumarin prophylactically, signs of thrombophlebitis developed in 2, an incidence of 1 in 136 patients. There were no fatalities or pulmonary emboli observed in the treated patients. The indications and contraindications for the prophylactic use of bishydroxycoumarin that had been established in these first 1,144 patients are outlined; they were rigidly followed in the selection of patients for anticoagulant therapy among the succeeding 1,556 consecutive patients. In this second series, 728 patients either did not have the indications for the therapy or had definite contraindications to its use. In this untreated group, signs and symptoms of thrombophlebitis occurred in two patients, an incidence of 1 in every 264 patients (0.27%). Strict adherence to the indications and contraindications for the selection of patients for therapy resulted in a lowering from 4% to 0.27% the incidence of postoperative thromboembolic complications in the untreated group of patients. The remaining 828 patients had definitely recognizable indications for the therapy and were given 200 to 300 mg. of bishydroxycoumarin the morning of the surgical intervention, and an additional 100 to 200 mg. was administered on the first postoperative day and none to 100 mg. on the second postoperative day. Daily prothrombin times were obtained and the daily maintenance dose was regulated according to the prothrombin time. Once the response of the patient to the drug was ascertained, the prothrombin time was checked two to three times a week and minor adjustments in the daily dosage of the drug were made. The prothrombin time was maintained at two to three times normal, or from 25 to 40 seconds, and the prophylactic therapy was continued until the patient was fully ambulatory and for a minimum of 10 days. Among the total number of 1,100 patients (272 in the first series, and 828 in the second series) treated prophylactically with bishydroxycoumarin, clinical evidence of a thrombophlebitis developed in only 3 or an incidence of 0.27%. There were no instances of pulmonary embolism. Hemorrhagic episodes occurred in eight while they were receiving the anticoagulant therapy. In five of the eight patients these episodes were considered minor and cessation of the drug was adequate to control bleeding; in the remaining three, severe hemorrhagic complications necessitated the intravenous administration of large doses of vitamin K and transfusions of fresh whole blood.

Arterial Emboli—Aortography.—Translumbar aortography using Wylie's two needle technique was employed as a diagnostic aid in localizing arterial emboli in five patients. In the first patient the aortogram revealed a block in the left common iliac artery; a bilateral femoral block was demonstrated in the second patient, and block of the aorta from a saddle embolus was shown in the remaining three patients. Translumbar aortography is a safe procedure with few contraindications. It is simple to perform and requires only a few minutes. Hours may be saved in the management of an arterial embolus if there is any question of diagnosis. There is no need to delay operation to perform aortography. Anesthesia is started and aortography is done while the operating room is being set up for surgical intervention. If operation is indicated, anesthesia is continued and embolectomy is accomplished. The incision can be made for precise exposure of the embolus, with a minimum of operating time. Translumbar aortography aids in the management of peripheral arterial emboli, as it establishes the diagnosis and localizes the occlusion.

Radioiodine Treatment for Thyroid Cancers.—Uptake of radioactive iodine (I^{131}) in the primary or metastatic lesions of 47 patients with thyroid carcinoma was studied to determine the criteria for I^{131} therapy. Of the 47 patients, 13 had papillary carcinoma, 17 had adenocarcinoma with varying amounts of colloid formation, and 17 had carcinoma of the undifferentiated type. None of the patients with undifferentiated or papillary types of carcinoma showed any appreciable uptake of I^{131} in the primary or metastatic lesions. Eight of 17 patients with adenocarcinomas with colloid formation had metastases, and 3 of these showed sufficient uptake for I^{131} therapy to cause diminution in size of the lesions. In only these three patients who were benefited by I^{131} therapy was the necessary indication present, that of functioning metastases. When in only 3 of 47 patients, or 7%, the lesions are amenable to radioactive iodine therapy, even though dramatic, it is obvious that early and adequate surgery is still the best weapon against this form of carcinoma. If therapy with I^{131} is indicated, an initial dose of 25 to 50 mc. should be given. This will occasionally produce signs of tracheitis and subacute thyroiditis in about three to six weeks. This complication is easily tolerated by the patient. Six to eight weeks later a dose of 100 mc. may be given and repeated every four to six months until the desired effect is obtained or until the lesions no longer take up I^{131}. The patient will have myxedema in several months with this schedule and should be kept in that state if he can tolerate it. Intermittent administration of desiccated thyroid, 2 to 3 grains (0.12 to 0.20 gm.) became necessary to relieve a state of catatonic schizophrenia produced by prolonged myxedema in one of the author's patients.

Arterial Hypertension.—Fifteen outpatients between the ages of 36 and 59 years with arterial hypertension, with moderately good renal function, and without azotemia were treated with low sodium diets combined with cation exchange resins and hydralazine hydrochloride (Apresoline). The diets prescribed contained 1 gm. of sodium used in conjunction with 45 gm. daily of the cation exchange resin, Resodec, or 48 gm. daily of carbocrylamine resin (Carbo-Resin) taken after meals. These were supplemented by potassium citrate (1 gm.) and calcium lactate (0.06 gm.) in cherry syrup daily taken a few hours from the time of resin administration. Hydralazine was started with 75 mg. daily, was gradually increased to the point of effectiveness or intolerance (average dose 275 mg. daily), and was given before meals. The duration of combined therapy was 2½ to 10 months. Seven patients went through the complete cycle of therapies, five went through two-thirds of the cycle, and three were unable to tolerate hydralazine. Results showed that hydralazine combined with restriction of dietary sodium in conjunction with cation exchange resins is of value in obtaining a significant reduction of blood pressure and improvement in the cardiovascular and renal function in some patients with arterial hypertension in whom each of these agents used alone is of little or no value. Smaller doses of hydralazine may be used in this combined therapeutic program than are needed when the drug is administered alone. It seems logical that this effect should occur since one is attacking the hypertension with two means each of which has a different mechanism of action. Although the exact role of sodium in hypertension is not known there is some evidence that its depletion contributes to a decrease in peripheral vascular resistance, while the action of the hydralazine seems to be as a neutralizer of a pressor substance elaborated by the midbrain and perhaps of other humoral agents. Dibenzyline (n-phenoxyisopropyl-N-benzyl-β-chloroethylamine), an adrenergic blocking agent affecting sympathetic stimuli peripherally at the nerve endings, was given combined with a low sodium, cation exchange resin regimen in an average daily dose of 100 mg. to 34 outpatients between the ages of 38 and 60 years with hypertension. This combined therapy was used for two to six months. Of the 34 patients, 13 (38%) could not, or would not, take it long enough to permit evaluation of its hypotensive effect. In some of the remaining 21 patients dibenzyline administered in conjunction with low sodium, cation exchange resin therapy caused an additional fall in blood pressure below that attained with either type of therapy alone, but this gain was largely offset by the high incidence of undesirable side-effects and by the frequency of escape of the hypertension from the effect of the drug.

Hyperactive Carotid Sinus Reflex of Cardio-Inhibitory Type. —In 13 of 20 patients with auricular fibrillation, carotid sinus pressure produced no significant decrease in ventricular rate or symptoms other than those attributable to direct local pressure. In the remaining seven, six men between the ages of 40 and 81 and one 70-year-old woman, a hyperactive carotid sinus reflex of the cardioinhibitory type was produced almost simultaneously. In three of these seven patients, each with a history of syncope, ventricular standstill occurred. In the other four, two of whom had a history of recurrent episodes of dizziness and lightheadedness, the ventricular response was abruptly and significantly slowed and became regular. The auricular complexes appeared to be unchanged in frequency. The QRS complex became larger in two, an R-wave was abolished in one, and, in another, the configuration of complete left bundle branch block of 9 years' duration was transformed to that of normal conduction. Observations indicated that the predominant effect of carotid sinus pressure in these patients was upon the auriculoventricular node. It is important to recognize this carotid sinus syndrome because it alarms the patient and yet does not have as serious a prognosis as do other types of cardiac syncope. Therapy directed toward increasing myocardial efficiency and blocking the reflex arc somewhere in its course, may be effective in preventing recurrent attacks.

Pathological Anatomy of Eclampsia and Other Fatal Complications of Pregnancy.—From the cases of maternal deaths that occurred at the Boston Lying-In Hospital between 1930 and 1952 and in which necropsies were performed, 21, i. e., all cases of patients with toxemia, eclampsia, premature separation of the placenta, pituitary necrosis, bilateral cortical necrosis of the kidneys, and fibrin thrombi were studied. Eclampsia, bilateral renal cortical necrosis with premature separation of the placenta, and pituitary necrosis incident to pregnancy have been regarded as more or less distinct, separate clinical and pathological entities. The results of the authors' studies suggested that intravascular fibrin deposition in arterioles and capillaries throughout the body is responsible for the necrosis and hemorrhage seen in eclampsia, bilateral renal cortical necrosis, and pituitary necrosis associated with pregnancy. These cases are often accompanied by severe shock, hemorrhage, and anuria. Fibrinogenopenia and fibrinolysins develop in this group of patients. The pathological changes observed in the 21 patients and those in animals subjected to the generalized Shwartzman reaction were almost identical. It is, therefore, suggested that toxic material suddenly released into the maternal blood stream is responsible for the deposition of fibrin, the hemorrhages and necroses, and the acute clinical symptoms of shock, anuria and hemorrhage in toxemic patients with premature separation of the placenta and in eclamptic patients, and that these conditions are manifestations of the generalized Shwartzman phenomenon in human beings. In some cases the source of "toxin" may be a bacterial infection. In others, particularly those associated with toxemia of pregnancy, the "toxin" may be similar to the "menstrual toxin" described by the Smiths.

Remote Effects of Labor on the Child.—Of 135 children between the ages of 5 and 15 years who were selected to study the remote effects of labor, 47 were in the group of those whose mothers had been in prolonged labor with forceps delivery, 45 in the precipitate labor with spontaneous delivery group, and 43 in the natural labor with spontaneous delivery group. Physical, neurological, and psychological examinations indicated that precipitate delivery is likely to be more deleterious than the spontaneous natural delivery or prolonged delivery with instrumentation. Children whose birth had occurred rapidly showed a greater incidence of feeble-mindedness, a greater dispersion over the mental years in the intelligence test, a greater difficulty in completing geometrical figures, and a less well-developed laterality in the use of the hands, eyes, and feet. All of these results taken in their totality are more characteristic of children who have suffered brain injury. Most of the births in the precipitate group were among multiparous women. Eighteen of the mothers in this group were in labor less than one hour. Contractions occurring too frequently, and with too much force, reduce the oxygen supply and lead to anoxia. This in turn, can cause edema and hyperemia of the brain. Rupture of the bag of waters, with precipitate birth, produces sudden changes in intracranial pressure. Both of these conditions favor cerebral hemorrhage. Although the number of children studied was too small to warrant general application, the authors' observations suggested that if the child survives the neonatal period his chances of growth and development are equal after prolonged labor and forceps delivery and after natural labor with spontaneous delivery. Serious apnea after prolonged labor and forceps delivery does not contribute to abnormal mental development to a higher degree than spontaneous birth unaccompanied by apnea. A developmental clinic is needed to carry out this research. A correlation of birth experience with a continuous study of the growth and behavior pattern of the child may solve the problem of the effect of labor and delivery on the future development of the person.

Histoplasmosis Epidemics.—Etiological studies including skin tests, serologic tests, follow-up chest roentgenograms, and cultures of soil for pathogenic fungi were carried out in 13 epidemics of disseminated pneumonitis. Of 116 persons involved in the outbreaks, 94 were subjected to skin tests and all had positive results from the histoplasmin tests. Forty-four of 54 serums obtained from the 116 persons within three months of the onset of the epidemics showed high titer reactions to the complement fixation and precipitin tests, with falls in titer thereafter. Some serologic evidence of histoplasmosis infection was obtained in each epidemic. Pulmonary calcification was demonstrated in 61 of 73 persons who were examined roentgenographically at least four years after the onset of the epidemic in which they were involved. In 42 of these persons with calcification, the process was the disseminated miliary type. Histoplasma capsulatum was cultured from soil samples obtained at the place of infection (point source) in 11 of the 13 epidemics studied. Because of the occurrence of the disease in groups of persons with similar clinical findings and similar reactions to the etiological studies, these studies provide conclusive evidence that the epidemics were due to histoplasmosis.

Resection of Colon for Diverticulitis of Sigmoid.—Of 582 patients with diverticultis observed at the Massachusetts General Hospital between January, 1942, and March, 1953, 114 were treated by sigmoid resection, with operative mortality of 2.6%. Experience with these patients indicated that, where advisable, aggressive surgery was more effective than palliative procedures, such as exploratory laparotomy, often with incision and drainage, cecostomy, and colostomy. The opinion that surgery is not indicated in diverticulosis of the colon and uncomplicated diverticulitis is being revised. Indications for operation now include obstruction, bleeding, uncomplicated diverticultis, repeated attacks of diverticulitis while the patient is on a good medical regimen, diverticulitis in patients under 50 years of age, severe persistent deformity of the sigmoid on radiologic examination, development of urinary symptoms in the presence of diverticulitis, and suspected cancer. Resection and anastomosis can be performed in one, two, or three stages, depending on the general condition of the patient; the three stage operation is recommended for patients with perforation, fistula, or obstruction.

Direct Surgery of Arteriosclerosis.—Five patients with degenerative arterial disease of the lower end of the aorta, three with obstruction and two with dilatation and aneurysm formation, were treated by resection of the aortic bifurcation and repair of the defect with a preserved homologous aortic bifurcation. During the time of clamping the aorta, the blood pressure was reduced by the anesthetist by means of Arfonad (d-3, 4[1′, 3′-dibenzyl-2′ keto-imidazolido]-1, 2 trimethylene thiophanium d-camphor sulfonate), recommended as a means of reducing the trauma caused by the aortic hemostatic instrument. The over-all result of this treatment was satisfactory. Two grafts were successful in restoring blood flow to both extremities, while, in three, restoration was obtained on one side only. No deterioration of the repair was noted.

Physical Treatment of Respiratory Paralysis in Poliomyelitis.—The treatment program of poliomyelitis patients with respiratory paralysis, which has been adapted at an Institute for Neuromuscular Rehabilitation in California, is presented. This procedure includes (1) making repeated measurements of tidal air and vital capacity, (2) proper positioning of the patient, (3) treatment of intercostal spasm by means of packs and early and continued manual mobilization therapy, (4) using positive intrapulmonic and negative intratank respiratory pressures, and (5) supplemental respiratory exercises, combined with the use of an abdominal binder when indicated. Other measures included (6) pulmonary ventilation exercises, used separately, with the positive pressure breathing equipment provided either by the attachments of the tank type respirator or by the Bennett flow sensitive positive pressure apparatus, or using combined negative intratank and positive intrapulmonic pressures and (7) treatment of muscle paresis and paralysis by means of manual resistive exercises, combined with reinforcement exercises to augment synaptic facilitation of the remaining undamaged motor neurons. The combination of manual resistive exercises and reinforcement techniques is believed effective in restoring adequate pulmonary ventilation. Three additional therapeutic techniques that are not customarily employed in the physical treatment of poliomyelitis patients with respiratory weakness are described: (*a*) early and prolonged mobilization therapy, (*b*) early and extended use of manual resistive exercises, and (*c*) early and continued use of reinforcement techniques to facilitate the motor response of the muscles of respiration; the combination of manual resistive exercises and reinforcement techniques is used as the basic principle of neuromuscular reeducation. Clinical observations were recorded on 12 patients with respiratory muscle paralysis. Sufficient reserve to discontinue the use of the respirator developed in all but three. One patient continues to use the tank type of respirator only at night, and the other two patients use the chest respirator at night. Poliomyelitis patients with respiratory paralysis can be treated effectively during the convalescent and chronic stages by the treatment program presented in this paper.

Mineral Springs.—Kornblueh and Piersol feel that it is the responsibility of those interested in physical medicine to place balneology on a rational and scientific footing. Preparatory field work includes location of mineral springs, physical, chemical and bacteriological examination of waters, determination of their physiological and therapeutic potentialities, and evaluation of mineral water on the basis of experimental laboratory studies and controlled clinical investigations. A survey was made of the mineral springs in Pennsylvania. This survey located 29 spas with hotel accommodations that existed in Pennsylvania at different periods during the last 200 years. Only three of these spas were active in 1952. The authors feel that good mineral water in sufficient amounts, free of contamination and impurities, is a valuable therapeutic asset, but the proper evaluation of water requires the cooperation of various scientific groups. The restorative and rehabilitative possibilities offered in the environment of a spa are not met by other medical facilities. Balneology offers effective therapeutic approaches to many somatic and psychosomatic problems in medicine.

Mitral Commissurotomy in Aged Patients.—Mitral commissurotomy was performed in 20 patients (out of 400 consecutive cases) between the ages of 50 to 61 years. These patients were greatly incapacitated. A definite history of rheumatic fever and/or chorea in childhood was found in eight patients. The symptoms, however, had not appeared in them until the later decades of life. Systemic emboli had occurred in five patients, four of whom had cerebral emboli besides emboli to the abdomen or legs. The diagnosis was "pure" mitral stenosis in 11 patients and mitral stenosis associated with mitral insufficiency in 9. At surgery a thrombus was found in the left auricular appendage and/or left auricle of nine patients. Four of them had a preoperative history of arterial emboli. The clot was removed by auricular appendectomy in seven. Calcification was present in 13 of the 20 valves, and it was excessive in five. The size of the valve orifice was less than 1 cm. in diameter (diameter of a cigarette) in 17 patients and slightly larger in 3. The valve leaflets were separated to a width of 3 to 4 cm. in 12 patients, 2.5 cm. in 7, and 1.5 to 2 cm. in 1. Clinically significant insufficiency was never produced even in those patients who had minimal insufficiency prior to commissurotomy. All the patients were discharged 10 to 21 days after the operation except one whose left leg had been amputated. Results were excellent in six patients who are leading a normal productive life; they are taking a maintenance dose of digitalis but do not need excessive salt restriction or use of mercurial diuretics. Nine are improved, but in addition to digitalis they must also remain on a low sodium diet and sometimes resort to mercurial diuretics. Three patients were not benefited. Of these, one refused to follow instructions, one had a dynamic mitral insufficiency and marked right ventricular enlargement, and one had a heavily calcified valve, making it impossible to separate the leaflets adequately. Two other patients who had had chronic congestive heart failure for over two years with a marked enlargement of the heart and liver died three and eight months after commissurotomy. These results indicate that mitral valve surgery can be performed without unusual morbidity and mortality in selected patients over 50 years of age who, therefore, should not be denied surgery merely because of age. Prognosis rests mainly on the size of the heart. Best results are obtained in those with slight to moderate right ventricular enlargement. Patients with pronounced enlargement of the right ventricle especially if associated with an enlarged left ventricle and/or massive dilatation of the left auricle are poor risks.

Aschoff Bodies in Auricular Appendages of Patients with Mitral Stenosis.—The authors made a biopsy study of 183 left auricular appendages removed during interventions for mitral stenosis in patients who had no clinically obvious signs of active rheumatic fever. They found Aschoff bodies in 45.4% of the appendages. They report on the correlation of the clinical features with the histological findings. There was no definite correlation between the Aschoff lesions and the usual clinical or laboratory criteria of rheumatic activity. The erythrocyte sedimentation rate, the antistreptolysin-O titer, and the electrocardiograms (apart from the significance of rhythm) were found to be of no value as evidence of rheumatic "activity." The heart rhythm of the patients was an important factor since the incidence of positive biopsies was lower in patients with auricular fibrillation. Of 95 patients with auricular fibrillation, only 16 (17%) had Aschoff lesions against 65 (76%) of 86 patients who had normal sinus rhythm. Fibrillation correlates well with the presence of intra-auricular thrombus, and since this is uncommon in hearts with Aschoff lesions these findings seem to be justified. Age was also an important factor, since the frequency of Aschoff lesions decreased with advancing age. They were found in 73% of the patients between the ages of 20 to 30 years and in only 8% of those over 50 years. The Aschoff lesions did not show seasonal variation. The significance of these biopsy findings in relation to clinical rheumatic fever is difficult to explain. There is nothing in this study to prove or disprove a relationship between the Aschoff lesions and a continuing active rheumatic state. If this state does represent "smoldering" rheumatic carditis, then the currently available clinical techniques are not specific enough to demonstrate it. Studies of hearts with other forms of rheumatic valvular disease might shed some light on this problem.

Spontaneous Diabetes Mellitus in Dogs.—In dogs, spontaneous diabetes differs in no important respect from permanent experimental diabetes produced by alloxan (2,4,5,6[1,3]-pyrimidinetetrone), pituitary extracts, or subtotal pancreatectomy. Perhaps it is too much to say that it does not differ materially from human diabetes, but the resemblance, with the possible exception of the vascular complications, is close, even to its predilection for middle-aged or elderly females. The disease is apparently associated in all cases with extensive histological abnormalities of the islands of Langerhans or of the pancreas as a whole and with a marked depletion of extractable pancreatic insulin. The cause of beta cell failure in dogs is no more apparent than in man. The pituitary bodies were grossly normal when removed; this organ shows no consistent change in human diabetes. The adrenal glands, although exhibiting nodular hyperplasia, were not significantly different from those of nondiabetic old dogs. Nothing is known about the genetic aspects of diabetes in dog. Fibrous arteriosclerosis, not atherosclerosis, is the rule and is doubtless related more to the age of the animals than to the influence of diabetes. Of particular interest are the glomerular lesions scarcely distinguishable from those of intercapillary glomerulosclerosis in man that were found in one dog. If these two types of lesions are considered counterparts in dog and man, certain questions arise: 1. Are 12 months of poorly controlled diabetes enough to have produced such changes? 2. If so, why have they not been found to this degree in dogs with uncontrolled experimental diabetes of more than three years' duration? 3. Is it possible, as has been hypothesized for man, that spontaneous diabetes carries with it the tendency toward vascular disease and that hyperglycemia and its concomitants alone, although perhaps augmenting it, do not actually cause it? 4. If this is true, why did true atherosclerosis, as distinct from fibrous arteriosclerosis, not appear in the present case? 5. Since the Kimmelstiel-Wilson syndrome in patients rarely occurs without retinopathy, why was the retina spared in this dog? Further studies are needed to find these answers.

Factors Affecting the Islets of Langerhans.—Factors that reduce islet activity and in young rats depress islet growth are restriction of caloric intake or carbohydrate intake, administration of large amounts of insulin, and removal of the pituitary gland. Factors that stimulate islet activity and in young rats decrease islet growth in both intact and hypophysectomized young rats are high carbohydrate intake, continuous injection of glucose, injections of anterior pituitary extract, injections of growth hormone preparations, injections of corticotropin (ACTH), and thyroid administration. Injections of cortisone are stimulating only in rats that have had hypophysectomy. Estradiol benzoate, diethyl stilbestrol, and progesterone are stimulators in intact rats; they have not been tested in rats that have had hypophysectomy. The stimulating action of testosterone is not significant in intact rats, and has not been tested in other rats. The fact that these various substances seem capable of stimulating islet growth probably means that their effects are brought about through some final common path. It seems likely from other work that the materials that stimulate the growth of the islets do so because they increase the need for endogenous insulin, though the manner in which this requirement is transmitted to the pancreas is not known. Excessive stimulation of the islets under some conditions can lead to degeneration and finally to disappearance of the insulin-secreting cells. Factors reducing islet activity can prevent this excessive stimulation and protect the islets.

Effect of Antimicrobic Agents on Artificial Pneumothorax.—Of 266 patients with pulmonary tuberculosis in whom artificial pneumothoraces were induced, 105 were submitted to 116 consecutive pneumothoraces (group A) without specific medication and 82 patients to 82 consecutive pneumothoraces (group B). All but seven of the patients received *p*-aminosalicylic acid both before and after induction of pneumothorax; the remaining 79 patients were submitted to 85 consecutive pneumothoraces (group C), with *p*-aminosalicylic acid and dihydrostreptomycin given in combination both before and after induction of pneumothorax. These three groups of patients were observed for six months after the induction of the pneumothorax to study the effect of the antimocrobic agents on the artificial pneumothorax therapy. A free space was found at induction or was obtained after adhesion section in 42% of group A, in 57% of group B, and in 56% of group C. "Spontaneous" pleural effusion (appearing before adhesion section or more than two months afterwards) occurred in 15% of group A, 9% of group B, and 5% of group C. Pleural effusions followed adhesion section within two months and were considered to be caused by the intervention in 23%, 18%, and 15% of the respective groups. Pleural effusions persisted for more than two months in 27%, 15%, and 7%. Empyema developed in 3% of the patients in group A, but in none of groups B and C. Impairment of ventilatory function due to pleural effusion was observed in 16% of group A; in some of these patients the impairment was severe. In groups B and C only 11% and 5%, respectively, showed any functional damage, and this was invariably slight. These results indicate that artificial pneumothorax can be undertaken with the aid of the new specific drugs, without the risk of pleural effusion, empyema, and permanently impaired ventilation following pleural effusion.

Medicine at the Crossroads: 1933-1953. L. M. Orr.—p. 245.

Treatment of Creeping Eruption.—Creeping eruption, in the form of larva migrans or creeping ancylostomiasis, is a form of parasitic infestation of the skin caused by the filariform larva of the dog and cat hookworm, Ancylostoma braziliense.

This larva can penetrate the human skin on direct contact with contaminated soil and produce a disturbing skin lesion characterized by serpiginous burrows and itching. The worm, in the deep layers of the skin, has previously been extremely difficult to eradicate, and therapeutic attempts have produced scarring and disability in excess of that caused by the worm. Kelley and his associates now employ the filaricide, Hetrazan, which is available in the form of the dihydrogen citrate salt of 1-diethylcarbamyl-4-methylpiperazine. Toxicity is negligible in therapeutic doses. It was at first available in 50 mg. tablets, and later as a syrup containing 120 mg. per teaspoonful, which is a more convenient dosage form. The histories of seven patients with creeping eruption are presented. Side-reactions seem to be of no great consequence. Three of the patients experienced nausea with each dose, but were able to complete the course. The nausea was reduced by taking the drug immediately after meals. The effective dose seems to vary regardless of the age or the severity of the infestation. A fairly large dose for a relatively short time seems most satisfactory. The originally recommended dose of 2 mg. per kilogram of body weight given three times a day was found too small in most cases. The author now prefers to give 9 or 10 mg. per kilogram per dose, administered three times a day immediately after meals, for a period of five or six days. This is most conveniently given in the form of the syrup.

Streptococcus Toxin-Antitoxin in Experimental Production of Arterial Sensitization.—Thirty rabbits were passively immunized with 1,500 United States Public Health Service (U.S. P.H.S.) units of Streptococcus antitoxin (horse globulin) and were given two to six hours later a 15,000 skin test dose of Streptococcus erythrogenic toxin in divided doses. These animals were killed 24 hours later and sections were taken for a microscopic study. Microscopic pathological lesions were observed in 14 rabbits. These involved the small pulmonary arteries, pulmonary arterioles, and occasionally the pulmonary venules. The lesions consisted chiefly of a periarteriolar and a mild panarteriolar infiltration especially of eosinophils and to a lesser extent of lymphocytes, plasma cells, and neutrophils. Five rabbits received a similar dose of Streptococcus antitoxin alone, and five received the same dose of Streptococcus toxin alone. Ten rabbits were passively immunized with Streptococcus antitoxin and five of these were challenged with diphtheria toxin and the remaining five with Veldee mediums. Five rabbits were passively immunized with tetanus antitoxin and five received normal horse serum prior to the administration of challenging doses of Streptococcus erythrogenic toxin. In all 30 of these animals there were no pulmonary vascular lesions observed after 24 hours. The lesions of pulmonary periarteritis and panarteritis in those rabbits passively immunized against and challenged with Streptococcus erythrogenic toxin were less frequently and uniformly produced and were of less severe degree of involvement than found in a series of rabbits that had been passively sensitized against and challenged with horse serum. Apart from quantitative differences, qualitatively the lesions were histologically identical in rabbits subjected to passive sensitization and challenge, regardless of whether the antibody-antigen system employed was homologous antihorse serum-horse serum or heterologous species Streptococcus antitoxin-erythrogenic toxin.

Congenital Hyperhidrosis.—The occurrence of congenital hyperhidrosis is reported in a 9-year-old girl. Excessive sweating on both the volar and dorsal surfaces of the hands and feet were the significant findings on admission to the hospital. The hands and feet were cooler than the other parts of the body, and the distal portions of the fingers and toes were pale with smooth, thin skin. There was symmetrical decreased vascular pulsation and blood flow in fingers and toes. Vasodilation resulted from right tibial procaine hydrochloride block as evidenced by flushing and increase of pulsation, blood flow, and skin temperature. Sweating of the right foot was completely abolished by the block. Studies with subcutaneous injections of the adrenolytic agent Hydergine, a mixture of dehydrogenated ergot alkaloids with a sympatholytic effect, blocking sympathetic nerves at the neuroeffector junction, demonstrated similar simultaneous changes in all four extremities. Methantheline (Banthine), owing to its effect of blocking the parasympathetic nerves, was shown to moderately decrease, but not to abolish, sweating of the hands and feet. The effect of psychic stimulation was striking, with apprehension resulting in decreased skin temperature and profuse sweating of hands and feet. On discharge from the hospital, the patient was given 1 gm. of Hydergine orally every three hours during the day and 50 mg. of methantheline three times daily. During the next nine months the child experienced pronounced relief. Despite excessive hot weather, her hands and feet remained almost completely dry with skin pallor replaced by a natural pink color. Until the recent development of satisfactory sympatholytic agents, surgical sympathectomy was the only effective treatment. The differing modes of action of Hydergine and methantheline suggested their simultaneous use in the authors' patient, which was apparently of more value than when either drug was used alone. Although the results obtained with combination of these drugs were extremely satisfactory, cumbersome daily administration of the drugs will have to be continued indefinitely and, therefore, the question of sympathectomy may be seriously considered in the future. It is possible that discovery of other new drugs that have an adrenolytic effect may obviate the need for sympathectomy.

Chorea Minor.—Corticotropin (ACTH) combined with co tisone in various ratios ranging from 1:1 to 1:3 was give every six hours to six children between the ages of 7 and years with chorea minor. Administration of the drugs w continued until symptoms cleared completely; this occurr in 8 to 48 days calculated from the day of admission, wi the drugs administered for from 7 to 32 days. Better resul appeared to occur with combinations in which the cortic tropin-cortisone ratios approached each other. There w evidence of moonfacies in all patients from 8 to 23 da after treatment. Three patients had systolic hypertension, b all undesirable side-effects subsided on cessation of medicatio Comparison of the results obtained in the authors' patien with those previously reported by other workers in patien who were given either corticotropin or cortisone alone reveal the superiority of combined hormone therapy over individu administration of these drugs in chorea. However, this findi should not be considered as an implication that hormo therapy is the preferred or acceptable one for this conditio larger series must be studied and more work must be do on the variations of the combination to determine the optimu ratio before any dependable conclusions can be reached.

Liver and Kidney Function in Hexamethonium-Induced Hypotension.—The physiological effects of hexamethonium-induced hypotension on the liver and kidneys were studied in 11 normal dogs and 8 women with a diagnosis of cancer of the genital organs. The renal function was impaired in a few of these patients. Premedication, anesthesia, and position were used to stimulate actual clinical conditions. Since control tests indicated little effect from the anesthetic agent, the changes can be ascribed to the effects of the induced hypotension. Six of the dogs in which hypotension was maintained for from 30 to 105 minutes were killed two to three days later. There was moderate to severe congestion of the liver in all but one dog. Focal pericentral vein necrosis was found in the liver sections of one dog and foci of hepatic cells swollen with glycogen in those of another. Biopsy specimens removed from these two dogs under anesthesia before administration of hexamethonium had been negative. There was marked congestion in the spleen of all the dogs and in the kidneys of most. The other organs were normal. In contrast to these findings, there was no significant variation between values of serum bilirubin, cephalin flocculation, and thymol turbidity determined in the women before and after hypotension was induced. These differing results are ascribed to the fact that a reduction of the systolic blood pressure below 60 or 50 mm. Hg could not be reached in most of the women despite complete ganglionic blockade. Other authors have reported that a systolic pressure of 60 mm. Hg is the critical point below which the liver is impaired. The results of the evaluation of the kidney function were similar in the two groups. In the dogs there was a marked decrease in the inulin clearance values after the systolic pressure had reached 60 mm. Hg and in the *p*-aminohippurate clearance values after it had reached 50 mm. Hg. The glomerular filtration rate and the renal blood flow decreased in the women as soon as the pressure fell much below normal values. The degree of impairment corresponded to the level of blood pressure reached and remained constant at a given level of hypotension. The clearance values improved as the blood pressure returned to normal either because the drug failed to maintain a persistent lower tension or following elevation of the feet. Renal blood flow was restored more rapidly than glomerular filtration rate. Normal values were obtained more slowly in patients who had impaired renal function before the experiment. Sodium and potassium excretion was reduced in all the women as the blood pressure dropped. The author concludes that hexamethonium-induced hypotension below a minimum of 60 mm. Hg presents a definite risk of kidney and liver function impairment. Since the danger is much greater in patients with renal or hepatic disease, this technique should be limited to persons whose cardiovascular, renal, and hepatic function is good.

Familial Benign Chronic Pemphigus.—The occurrence of familial benign chronic pemphigus, a familial disease of unknown etiology, is reported in seven men and one woman between the ages of 25 and 56 years. These eight cases were observed in the course of 13 years. There were two pairs of brothers among the men. Cultural studies of the bullae, vesicles, and ruptured lesions failed to demonstrate any causative organism. The usual blood and urine studies were normal. The patients were annoyed and nervous during the attacks but were able to follow their usual occupations. The attacks are less frequent and less severe as the years go by. The author has never seen familial benign chronic pemphigus in a Negro, although there is a large Negro population in his home town.

Oxytetracycline in Treatment of Dermatoses.—Oxytetracycline (Terramycin) was employed for the treatment of 1,194 patients with various dermatoses. Of these, 466 received the drug by mouth and 728 were treated with the local application of 3% ointment. Oral administration in adults was practiced with an initial dose of 2 gm. of the drug followed by 0.5 gm. four times daily. If there was no improvement after two or three weeks of this treatment, the administration of the drug was discontinued. Children under 10 years were given an average dose of 50 mg. per kilogram of body weight divided in four doses in 24 hours. Of the 466 patients given the drug by mouth, 129 were definitely benefited, 197 were occasionally, temporarily, or partially improved, and 140 were therapeutic failures. Definite benefit from oral administration of oxytetracycline resulted in all conditions in which pyogenic organisms were the primary cause of the disease. Oral administration of the drug was of value in the treatment of secondary pyogenic invasion of eczema, epidermophytosis, stasis ulcers, and seborrheic dermatitis but had no beneficial effect on the primary disease. The lesions of granuloma inguinale healed rapidly after the institution of oxytetracycline orally, and no relapses were noted. The lesions of erythema multiforme responded to treatment with oxytetracycline capsules in 17 of 24 patients. No blood dyscrasias were observed in the 466 patients. Of the 728 patients who received local application of oxytetracycline ointment, 302 were definitely benefited, 251 were occasionally, temporarily, or partially improved, and 175 were therapeutic failures. There was rapid healing of pyogenic infections, such as impetigo contagiosa and ecthyma. Oxytetracycline ointment was also of value in the treatment of many skin eruptions complicated by secondary pyogenic invasion but had no effect on the basic dermatosis. A contact sensitivity to the drug developed in 11 patients treated with oxytetracycline ointment. All these patients gave a positive reaction to patch tests with oxytetracycline powder, establishing this as the cause of the reaction, while they had negative results from control tests of the lanolin and petrolatum ointment base. Oxytetracycline is a valuable addition to the drugs already in use for the treatment of skin diseases, but, as with all antibiotics, it should be used only where there is a specific indication.

Surgical Treatment of Aneurysm of Abdominal Aorta.—Resection of fusiform aneurysm of the abdominal aorta with restoration of normal blood flow by means of an aortic homograft was performed in seven patients between the ages of 47 and 74 years. The aneurysm in all but one of the patients was of arteriosclerotic origin and in all was located in the segment of the aorta below the origin of the renal arteries, fortunately the most frequent site of aneurysm of the abdominal aorta. One of the seven patients died on the 13th postoperative day of progressive uremia and secondary hemorrhage. All the other patients tolerated the operation well and showed excellent early results. The aneurysm in two of the patients had been wrapped with polythene film containing dicetylphosphate 13 months and 7 months, respectively, prior to resection. The gross and microscopic findings in both cases cast much doubt on the efficacy of this treatment. Aneurysm of the abdominal aorta is a serious condition with grave prognosis; for this reason and because most forms of therapy that have been previously employed are not considered satisfactory, a more aggressive attitude directed toward removal of the diseased tissue is advocated. Although final evaluation of resection of the aneurysm with restoration of continuity with homograft must await further observation and experiences, on the basis of the immediately gratifying results obtained in the seven patients reported on in detail and on five additional patients who recently submitted to this treatment with no deaths and no complications, the authors believe that it is the procedure of choice in the treatment of this condition.

Surgical Treatment of Coarctation of Aorta.—The author reports on 22 patients between the ages of 16 months and 31 years operated on for coarctation of the aorta. In 20 an end-to-end anastomosis and in 2 aorta to subclavian artery anastomosis was performed. Four of the 22 patients had cardiac failure, 6 aortic regurgitation, and 1 mitral stenosis. The combination of aortic regurgitation and stricture would seem to place an undue stress on the heart, for by x-ray examination five of these six patients were observed to have cardiac enlargement. There were five other patients with cardiac enlargement not associated with aortic insufficiency. There was a significant reduction in the size of the heart after the surgical intervention in the 10 patients with enlarged hearts who survived. Of the series, 19 had survived and the only postoperative complication that had occurred was a subarachnoid hemorrhage in one on the fourth postoperative day. In 19 patients followed after the operation for coarctation of the aorta, there was a reduction in the systolic pressure to normal, giving the best indication of a successful repair and restoration of an adequate aortic lumen. Reduction the abnormal stress on the vascular wall at the site of t anastomosis, as well as the removal of the necessity for large volume to pass through collaterals, are important assessing the result of operation. Surgical intervention indicated in nearly one-half of the cases of coarctation the aorta in order to prevent vascular rupture or infection the region of the coarctation. Coarctation when complicat by some other anomaly of the heart or great vessels presen great risk of heart failure. The removal of the coarctation w improve cardiac function in instances of congestive failu when a coarctation of the aorta is associated with anoth defect. The combination of coarctation of the aorta and son other anomaly of the heart or great vessels constitutes t strongest indication for surgery. The operation is mandato in the very young patients when adequate circulation cann be obtained and development is retarded. There are technic advantages in performing the operation when the patients a of the ages of 5 to 10 years. The operation becomes mo hazardous in patients over 30. The mere diagnosis of coarctation associated with mild systolic hypertension does not constitute an unequivocal indication for operation in this ag group.

Polyvinylpyrrolidone in Treatment of Shock.—Polyvinylpy rolidone (PVP-Macrose) was used as emergency treatment i 35 patients with traumatic and hemorrhagic shock of a degrees of severity associated with head injuries, multip fractures, and penetrating wounds of both chest and abdome Some of the patients required blood and plasma subsequentl Of the 35 patients, 34 were treated at the hospital and 1 the scene of a highway accident. The polyvinylpyrrolido solution in volumes of from 1,000 to 2,500 cc. was infuse within periods varying from 45 minutes to 4½ hours. Th clinical responses were judged to be good in all patients, evidenced by prompt rises in blood pressure, improvement i vital signs, decrease in the venous hematocrit and plasm proteins, as well as dilution of the capillary blood as observe in the decline of the specific gravity of peripheral blood. Th urinary output was satisfactory in all. No sensitivity reactio either immediate or delayed were observed. There were n toxic reactions. No interference with blood typing, coagula bility, or depression of hematopoiesis occurred. Althoug polyvinylpyrrolidone is slightly hyperviscous, it flowed readil in the near-freezing weather when injected at the scene o the highway accident. The authors' results fully substantiate previously reported experiences and indicated that polyvinyl pyrrolidone is a valuable adjunct in the emergency treatmen of both traumatic and hemorrhagic shock.

Epituberculous Shadows.—Klinke and Huth point out that cases of epituberculosis, which at first give the impression of clinical uniformity, later on progress in a diverse manner. This suggests diverse anatomic processes. This form of tuberculosis is seen chiefly in young children between 9 months and 4 years of age and almost never beyond the age of 6. This suggests that epituberculosis may be a tuberculous reaction typical of this age group. The same has been assumed with regard to scrofula, in fact the clinical similarity between these two diseases has led some to suggest that epituberculosis is scrofula in the lungs and a manifestation of exudative diathesis. Experiments on animals proved that epituberculosis is a mixture of atelectasis and hyperergic inflammation. These two factors explain the different modes of pathogenesis and the varying courses of epituberculosis. 1. There is the atelectatic form without or with only slight hyperergic reaction. This form develops when the bronchus is compressed by a bronchial lymph node and when there is only slight or no toxic invasion. This form appears suddenly and also subsides rapidly, somewhat like a purely mechanical atelectasis. 2. There is compression as explained under point 1, but, as the result of the invasion of toxins into the atelectatic region, there is a stronger hyperergic reaction. 3. The debris of a lymph node that contains few or no bacilli perforates into the bronchus; a hyperergic inflammation and atelectasis develop. The clinical symptoms are the same as those that develop under the conditions described under point 2. Recovery involves shrinkage of the atelectatic process. 4. There is invasion by infective material, with simultaneous hyperergic reaction. In these cases, the clinical picture resembles that developing under the conditions described under points 1 and 3. Partial caseation and its sequelae follow. Transitional and complicating forms also occur. The authors conclude that epituberculosis represents a hyperergic, exudative reaction, which occurs particularly in young children who at the same time have atelectasis either as the result of a compressing bronchial lymph node or because the bronchial mucosa is swollen because the bronchus has been invaded by a perforating lymph node.

*Clinical and Statistical Study of Gastroduodenal Hemorrhages. A. Parentela and A. Stochino.—p. 209.

Hemorrhage from Gastric and Duodenal Ulcer.—From 1938 to 1951 a total of 1,845 patients with ulcers were admitted to the surgical clinic of the University of Rome. The authors studied in particular the 315 (17.07%) patients of this group in whom the ulcer was complicated by hemorrhage. They found gastric ulcer in 55, duodenal ulcer in 208, postoperative peptic ulcer in 31, gastric ulcer with duodenal ulcer in 8, malignant ulcer in 7, perforating ulcer in 2, and ulcer secondary to gastroenterostomy in 4. They divided the patients into three groups according to whether the hemorrhage did not produce shock (moderate hemorrhage), produced severe collapse (massive hemorrhage), or did not produce shock but reappeared frequently during the course of the disease and caused a severe anemia (repeated hemorrhage). Massive hemorrhage was found in 18.18% of the patients with gastric ulcer and in only 9.58% of those with duodenal ulcer. This difference is ascribed to the fact that in patients with gastric ulcer the bleeding is nearly always due to an erosion of the pancreaticoduodenal, the right, or the left gastric artery or their main branches, whereas in patients with duodenal ulcer it is frequently due to an erosion of the small vessels of Meissner's plexus. The percentage of massive hemorrhage was not greater in older persons, as is commonly believed. However, the mortality rate for massive hemorrhage is generally higher in older persons, perhaps because of a deteriorated general condition. The hemorrhage was commonest in patients between 30 and 50 years of age, and it was found 5.1 times oftener in men than in women. Treatment of patients in whom an ulcer is complicated by bleeding should first be medical to prepare them for the intervention. Intervention should be performed only after the hemorrhage has been controlled and the patient's general condition improved. Early surgical intervention may be justified only in those patients in whom the clinical picture continues to deteriorate despite medical therapy. At the University of Rome this therapy consists of bed rest, proper diet, application of an ice bag to the epigastrium, administration of sedatives, and, most of all, repeated transfusions of small quantities of blood. Surgery was not performed on 83 patients because either they or their families refused it or because their general condition had improved or had remained unchanged. All these patients left the clinic, and three of them have since died. Gastric resection was the operation of choice for 182 patients. Gastroenteroanastomosis and vagotomy was performed in the others because of unfavorable local conditions. Eight of these patients have died. In two of them, the hemorrhage was associated with a perforating ulcer. Of the 11 patients who died, 54.54% were more than 50 years old.

Liver Extract, Folic Acid, and Vitamin B_{12} in Pernicious Anemia.—Comparative observations were made on 15 patients with pernicious anemia and signs of combined degeneration of the spinal cord. The patients either had not had a previous treatment or were in the course of a hematoneurological recurrence of the disease after discontinuation of treatment. They were observed in three groups of five patients each, according to the drug they received. The drugs were given intramuscularly, twice a week for a month, up to the following total doses: vitamin B_{12}, 0.1 mg., folic acid, 0.5 gm., and liver extract, 10 cc. (150 to 200 USP antianemic units). No additional treatment was given. The effects of the drugs were evaluated from the results of repeated hematological and neurological examinations. The drugs proved to be of value in the treatment of anemia, with equally good results from liver extract and folic acid and less markedly good results of vitamin B_{12}. Improvement in the red cell count was in correlation to the increase of hemoglobin. The effects of the drugs on the neurological syndrome were favorable. Folic acid proved to be less effective than vitamin B_{12}, but slightly more effective than liver extract. The course of pallesthesia paralleled improvement of the general neurological symptoms. Improvement of subjective symptoms was more marked than that of objective signs. The effect of the drugs on the neurological syndrome was in disagreement with those observed on the blood, as no correlation between the course of pallesthesia and the red cell count was observed. The three drugs caused improvement in the same degree of the dorsal funicular symptoms. The pyramidal symptoms greatly improved from the treatment with vitamin B_{12} or folic acid. The peripheral syndrome improved by treatment with vitamin B_{12} or liver extract. The best results with any of the three drugs were observed by the improvement of mental disorders, pyramidal deficit, hypotonia, and disorders of joint sensibility. The effects of the treatment on certain neurological signs were mediocre. The disorders of tactile sensibility grew worse with the treatment.

*Left Inguinal Hernia Involving Ovary, Tube and Uterus with Concomitant Absence of Vagina: Case. L. J. Torres Oliver.—p. 294.

Internal Genital Organs in Inguinal Hernia.—The subject of this report is one of a pair of identical twin girls 20 years old. She never menstruated. The other sibling had normal menstruation since the age of 13 years. The members of the family are all normal. Physical examination showed a girl apparently normal. She had a left inguinal hernia. The external genitalia and the urethra were normal. The hymen was well developed and totally closed. Rectal examination revealed absence of the uterus, tubes, and adnexa. By flexing the examining finger toward the examiner, it was observed that there was no vagina. Cystoscopy and pyelography showed a normal urinary apparatus. At operation to correct the hernia, rudimentary internal genital organs were observed. The pathological examination of the structures confirmed that the contents of the hernia consisted of a rudimentary uterus, an ovary, and a cystic fallopian tube. A laparotomy was not done to ascertain whether a right ovary, a right tube, and possibly an unicornus uterus were present in the inguinal canal or in the pelvis where they could not be reached by palpation. The case is discussed from an embryologic point of view. It is reported because inguinal hernias containing the internal genital organs are extremely rare in young girls and still more rare in women. Congenital abnormalities of the internal genital organs usually coexist with abnormalities of the urinary apparatus, but this case constitutes an exception.

Physiologically Low Leukocyte Counts and Sickness Absence in Radiation Workers.—The British X-Ray and Radium Protection Committee recommended that no person should be employed as an x-ray or radium worker if the general health or the total white blood cell and lymphocyte counts are below the lower limit of normal. The question was raised whether apparently healthy persons with a persistent low leukopenic count run a greater risk from exposure to radiation than those with counts in the so-called "normal" ranges. As far as the author is aware there is no evidence that such persons are, in fact, more susceptible to illness than those with counts at the usual higher levels. It was hoped that the medical and casualty records of the Atomic Energy Research Establishment employees with a physiological "leukopenia" might throw some light on this problem. The sickness and casualty records of 154 workers with persistently low leukocyte counts were compared with those of a group equivalent in number, sex and age, and with normal leukocyte counts. The casualty rates were similar in both groups, but the sickness rates of the low count group were significantly lower than those of the control group. It appears that a count persistently below 5,000 leukocytes or 1,500 lymphocytes is compatible with adequate resistance to infection, and with speedy response of the cellular defense mechanism, should infection occur. It is suggested that persons should not be barred from taking up work with ionizing radiations or radioactive isotopes solely on the basis of a physiological "leukopenia," but that the clinical assessment of general health should be the determining factor.

Changes in Prostatic Cancer After Adrenalectomy.—Franks says that bilateral adrenalectomy and orchidectomy was claimed by Huggins and others to have induced substantial clinical improvement in some cases of advanced prostatic carcinoma. The case presented by Franks concerns a 63-year-old man with an estrogen-resistant prostatic carcinoma. He was subjected to orchidectomy with no clinical improvement and finally to bilateral adrenalectomy. He died from an acute pulmonary infection 40 days after the second operation. Massive necrosis was found in the primary growth and in its metastases in the regional lymph nodes, liver, and lung. The author admits that necrotic areas are commonly seen in rapidly growing tumors, but that they do not as a rule involve both primary and secondary tumors simultaneously. No similar change has been seen in 29 other cases of prostatic carcinoma. Other possible causes are estrogens, cortisone, or insulin. The first can probably be excluded, because the cytotoxic changes it produces in prostatic cancer differ from those seen in this case. There is little convincing evidence that cortisone affects the growth of human prostatic tumors. It is also unlikely that insulin or the diabetic state could produce such massive necrotic lesions. The evidence suggested that the changes were caused by the removal of both adrenals. One further point of interest in this case is the absence of clinical evidence of regression in spite of the massive and widespread destruction of tumor cells.

Turner's Syndrome in the Female.—Jackson and Sougin-Mibashan present the histories of two young women and one 10-year-old girl in whom congenital agonadism was combined with developmental abnormalities. They emphasize that all congenital hypogonadism is not of pituitary origin. They describe the syndrome of primary ovarian aplasia. Turner, in 1938, first commented on the peculiar combination of webbed neck, short stature, and female infantilism. The important features of the condition are considered, and these are so characteristic that they present an unmistakable and diagnostic picture, plainly distinct from primary hypopituitarism, cretinism, eunuchoidism, or any other clinical state. Final proof of diagnosis should be sought in the urinary gonadotropin level and the demonstration of lack of ovarian tissue on laparotomy. In the two young women, the urinary level of follicle-stimulating hormone was high, a fact which exculpated the pituitary gland. Although the third patient was only 10 years old, the authors believe that the diagnosis of Turner's syndrome is definite. The curious clinical attributes of these patients have made them subject to much pathogenetic speculation. Most writers, accepting a genetic ovarian defect, agree that this alone cannot explain all the abnormalities. The occurrence of multiple congenital anomalies in the syndrome makes it likely that shortness of stature is but one manifestation of a germinally defective soma and is not directly related to the degree of ovarian agenesis. The presence of a little pubic and axillary hair and the urinary 17-ketosteroids in Turner's syndrome is ascribable to adrenal activity. The authors applied some of the recently adopted tests for adrenal cortical function to their first two patients and obtained normal responses.

Turner's Syndrome in the Male.—Ovarian agenesis, which is regarded as the causative factor of Turner's syndrome in women, means lack of graafian follicles and hence an absence of both ova and female sex hormones (germinal and endocrine deficiency). The affected person, therefore, is not fertile, does not menstruate, and lacks breast development, while her pituitary gland produces large amounts of gonadotropic hormone in an attempt to stimulate a nonexistent end-organ. It is not easy to define the homologous condition in the male because, in the testis, the germinal and the endocrine tissue (believed to be situated in the Leydig cells) are separate, so that a lack of development of either or both might be claimed to represent the sexual side of Turner's syndrome in the male. The authors feel that this explains why the five cases of male Turner's syndrome so far reported are less homogenous than those in the female group, since they show varying degrees of endocrine deficiency and will not, for instance, be expected necessarily to have high urinary gonadotropins. The Klinefelter, Reifenstein, and Albright syndrome is somewhat comparable, comprising azoospermia, small testicle, high urinary follicle-stimulating hormone, and gynecomastia. The basic lesion is different—hyalinization and sclerosis of tubules rather than lack of development. The authors list the "mixture" of germinal and endocrine defects in the previously reported cases of Turner's syndrome in males and describe a case that they regard to be an example. The man was short, his neck was webbed, and he denied ever having experienced sexual feelings of any kind and stated that he had never had an erection or an emission. Radiographs showed mild generalized osteoporosis. The high urinary gonadotropin content confirmed primary gonadal insufficiency.

Polycythemia, Leuko-Erythroblastosis, and Myelosclerosis.—The occurrence of polycythemia is reported in two women aged 69 and 48 and in a 51-year-old man. Leukoerythroblastic anemia and myelosclerosis subsequently developed after 4, 12, and 5 years, respectively. These three patients presented the characteristic symptoms, splenomegaly, and other physical signs and hematological features of polycythemia vera and resembled others described in that the polycythemic blood cell count figures were not very high. The syndrome, comprising leukoerythroblastosis, myeloid metaplasia, and myelosclerosis as revealed in the literature, has a varied clinical picture. It is thought to be distinct from myeloid leukemia. The authors point out that Vaughan and Harrison's view of the concomitant development from a common source—the primitive reticulum cell of Maximov—of extramedullary hematopoiesis and myelosclerosis following some, as yet unknown, stimulus offers a reasonable explanation of the events.

Poliomyelitis in Children Less than 6 Months of Age.—Of 82 cases of poliomyelitis in children less than six months of age in England and Wales during 1950, 77 were paralytic and 5 nonparalytic. The incidence of paralytic poliomyelitis in infants less than six months of age was 56.6% of what it would have been if such incidence had been equally distributed in six month age groups in children less than 15 years of age. Nonparalytic poliomyelitis is infrequently diagnosed in infants less than six months of age. Of the 82 patients, 19 died, a mortality rate of 23%. This mortality rate increased as age diminished. In infants less than nine weeks of age the mortality rate was 37.5%. Of the 58 children with paralytic poliomyelitis who survived, 30 were either very severely or severely paralyzed, and of these only 2 made a complete recovery. Of the 19 children who died, 4 were being entirely breast-fed at the time of death, 8 had been breast-fed for varying periods, 4 had never been breast-fed, and in the remaining 3 no information could be obtained. Of the 63 surviving children, 15 were entirely breast-fed, 32 had been breast-fed for varying periods, 10 had never been breast-fed, and of 6 no history was obtained. Of 13 infants less than six weeks of age with poliomyelitis, 6 died and 7 survived. Of the seven surviving, five were entirely breast-fed, and of these three had a mild attack. In the absence of a history of poliomyelitis in 76 of the 82 mothers, the authors were unable to make any deductions of value from these figures. The preparalytic symptoms were not diagnostic except of an acute infection in an infant less than six months of age.

*Liver Cirrhosis Associated with Gastroduodenal Ulcer. R. Antonini and F. Marinoni.—p. 184.

Liver Cirrhosis with Gastroduodenal Ulcer.—The files of the 6,859 patients on whom autopsy was performed at the University of Pavia Institute of Pathological Anatomy from 1901 to 1951 were reviewed. The cases in which liver cirrhosis was associated with gastroduodenal ulcer were studied in particular. The files of patients younger than 19 years were not considered, since these two processes are rare in the young. The authors found 175 cases of liver cirrhosis (2.55%) and 122 of gastroduodenal ulcer (1.77%). There were 142 cases of atrophic cirrhosis (Laennec's cirrhosis), 12 cases of biliary cirrhosis, 12 of initial cirrhosis, 6 of hypertrophic cirrhosis, and 3 of fatty cirrhosis. There were 87 cases of gastric ulcer, 31 of duodenal ulcer, and 4 of gastroduodenal ulceration. Cirrhosis associated with gastroduodenal ulcer was found in seven cases. This association was commonest among men; six of the seven patients had atrophic cirrhosis and four of them had multiple ulcers. A cause and effect relationship between the two processes is suggested. Some authors are of the opinion that in these patients the liver cirrhosis may be secondary to the ulcer. The authors state that portal hypertension or disturbance of biliary secretion due to liver cirrhosis may be the cause of ulcer formation.

*Arterial Pressure and Its Relationships to the Physical Constitution. L. Russo.—p. 86.

Blood Pressure and Physical Constitution.—The arterial pressure of 2,410 men, 20 to 30 years old, with normal cardiovascular and renal functions was studied to determine whether there is a relationship between a person's blood pressure and his physical constitution. The men were divided into three groups according to Pende's biometric system. By this method a person is classified on the basis of the ratios that exist between his height and weight and between his height and the perimeter of his chest. The systolic pressure was highest in vigorous men of average height and with well-developed muscles. It was also somewhat elevated in short robust men with well-developed muscles, although these had the highest diastolic pressure. It was especially high in those who were engaged in heavy athletics (wrestling and boxing). The author ascribes this to hypertrophy of the peripheral arteriolar bed caused by the heavy exercise. In general, all the robust persons with well-developed muscles had values of systolic and diastolic pressure that were more or less elevated regardless of the man's height. These findings proved that the blood pressure is also correlated with the neuroendocrinologic constitution of the person. Hyperadrenalism is characteristic of short vigorous persons of the muscular type who are generally predisposed to essential hypertension. In the author's study this type of man had not only increased systolic pressure but also, and chiefly, increased diastolic pressure. Hypercrinism is characteristic of robust persons of average height and with well-developed muscles. In this study men of this type had elevated blood pressure values. Tall, lean persons generally have normal (sthenic) or diminished (asthenic) function of the adrenal glands. In the author's study this type of man had low blood pressure values.

*Large Tonsils: Results of Serial Examinations. E. Müller.—p. 1017.

Hepatolienal Manifestations of Acute Anterior Poliomyelitis.—The occurrence of hepatitis is reported in 5 of 21 patients with acute anterior poliomyelitis who were admitted to the city hospital of Kassel, Germany, in 1952. Of the five patients, two were adults and three were children. Enlargement of the liver and the spleen was observed in all these patients; the hepatolienal manifestations disappeared after several days or weeks. Icterus occurred in two patients, on the 57th day of the disease in a 13-year-old boy and on the 7th day of the disease in a 3-year-old girl. It subsided after two and a half weeks in the older patient, and after nine days in the younger patient. Liver puncture, which was performed in one of the adult patients, revealed activation of the cells of the capillary walls and occasional periportal infiltration without invasio of the lobules and without impairment of the liver cells. Liv function tests (bilirubin in serum, Gros, Takata, thymol, an formol-gel) were performed but did not reveal any signs dysfunction, except for an increased amount of bilirubi in the blood serum and a slight drop of the Gros titratio numbers during the hepatolienal manifestations. In tw patients, the lymphocytes and the reticular elements (lymphoi cells) were increased simultaneously with the enlargement the liver and the spleen. It is suggested that poliomyeliti should no longer be considered a disease limited to th nervous system; on the contrary, poliomyelitis, similar other virus diseases such as epidemic hepatitis, infectiou mononucleosis, and epidemic parotitis, is to be considered disease of the entire organism, with involvement of th reticuloendothelial system. Depending on the various types the virus, one or the other of the organic systems may predominantly, but not exclusively, affected. The five patient reported on apparently presented a peculiar, previously un known form of poliomyelitis, rather than a double infection.

Large Tonsils.—Of 641 children between the ages of 5 and 1 years who were examined in school, 20 had had their tonsil removed; of the remaining 621, 87 (14%) had healthy tonsils 368 (59.3%) had chronic tonsillitis limited to the tonsils, an 166 (26.7%) had chronic tonsillitis, with peritonsillar adhesions. Extremely small tonsils were observed in 192 childre (30.9%) and extremely large tonsils in 112 (18.5%). The preoperative condition of the tonsils for which tonsillectomy was indicated was compared with the microscopic findings in the specimens after tonsillectomy. Follow-up examinations were carried out for six months to one year in 85 children who had tonsillectomies. The author's statistical data and the results of the various examinations suggest that extremely large tonsils do not occur in childhood as frequently as had been assumed. The examining physician may often be misled by an optical illusion, that is, the tonsils may appear very large only because the pharyngeal space of a child is relatively small and the tonsillar fossa flat. Hyperplastic tonsils are rare and were observed only in 2 (1.7%) of the 621 children. Form and size of the tonsils depend mainly on inflammatory factors beside hereditary factors such as growth capacity of the crypts and of the lymphatic tissue. The mere size of the tonsils as a mechanical obstacle requires surgical treatment only in exceptional cases. Removal of tonsils is indicated by a chronic condition of local inflammatory type or by general pathological phenomena with a local cause. Chronic tonsillitis nearly always is associated with swelling of the regional lymph nodes, which, therefore, are of significance in diagnosis, particularly in children. Enlargement and induration of lymph nodes subside partly or completely after the enucleation of the tonsils in a large number of cases. This applies to large as well as to small tonsils that had been affected by chronic inflammation.

Cardiac Catheterization in Patients with Acquired Valvular Defects.—According to Bayer and Wolter, defects of the mitral valve are primarily associated with characteristic changes in the pulmonary circulation. The pulmonary capillary pressure, which may be obtained by advancing the cardiac catheter into a peripheral pulmonary artery branch up to the occlusion of the lumen, is a useful measure for the pressure conditions in the left auricle. Despite the elevated pressure gradient of the flow into the left ventricle (ratio: pressure of left auricle and diastolic ventricular pressure), reduced expired volumes may be observed in most of the patients with severe mitral stenosis. Using the Gorlin and Gorlin formula, it is possible to calculate the remaining surface of the valvular orifice from the obtained data, namely, (1) the minute volume in relation to the diastolic time of the inflow (diastolic flow volume) and (2) the pressure gradient at the valve itself. Thus the exact degree of the stenosis can be determined. Besides the information gained from the recording of the pulmonary capillary pressure curve about the mean pressure in the left auricle, changes in the pulmonary capillary pressure curves due to mitral regurgitation may be detected. Observations in 140 patients with mitral stenosis and combined mitral defects showed that not only waves of pronounced ventricular reflux may characterize the mitral insufficiency, but already slight increases in the systolic portion of the curve may indicate the presence of regurgitation. The evaluation of such changes must be made carefully with consideration of additional factors, such as mean filling pressure of the auricle, mean pulmonary capillary pressure, and auricular fibrillation. The exact evaluation of the tracing of the pulmonary capillary pressure curve is of great importance because of the occasional absence of clinical symptoms of mitral insufficiency. In several patients with a diagnosis of mitral regurgitation based exclusively on the changes of the pulmonary capillary pressure curve, this diagnosis was established by surgical intervention while preoperative phonocardiographic recordings and roentgenologic examination did not suggest mitral insufficiency. In patients with pure mitral insufficiency in the state of left decompensation, pronounced increases of the mean pulmonary capillary pressure up to values of 30 to 45 mm. Hg, like those associated with mitral stenosis and combined mitral defects, were not observed. Increased pressure in the left auricle and herewith in the pulmonary capillary pressure curve occurred only with failure of the left ventricle and increased diastolic ventricular pressure. Corresponding changes in the pressure curve of the right auricle were observed in patients with insufficiency of the tricuspid valve. The results of catheterization of the heart may also establish the clinical suspicion of a relative pulmonary insufficiency occasionally associated with mitral stenosis. An increased amplitude with considerable drop in diastolic pressure may be observed as the essential criterium in the pressure curve of the pulmonary artery.

Licorice Juice in Treatment of Ulcer.—Juice of licorice added to the diet of eight normal guinea pigs for from three to four weeks produced a weight gain of 14% of the initial values. The weight gain in six control guinea pigs was only 6% of the initial values. Toxic manifestations never appeared, and autopsy (none of the animals died spontaneously) revealed no structural abnormalities. There was, however, a 16% decrease in the weight of the adrenal glands, and their morphological aspect resembled that which follows administration of large doses of desoxycorticosterone. It indicated a functional rest of the glomerular zone. The authors produced acute peptic ulcers in 14 guinea pigs by an intensive stimulation of the gastric secretion with administration of large doses of histamine. The general toxic actions of the drug were blocked by concurrent administration of histamine-antagonizing agents. Then eight of these animals were given juice of licorice in doses of 2 gm. per kilogram of body weight daily for 30 to 36 days. The secretion of the gastric mucosa was not inhibited nor was the formation of ulcer prevented. In vitro studies on the intestine removed from guinea pigs revealed only a slight antispastic action of the juice. The authors gave orally 20 to 25 gm. of juice of licorice in 100 cc. of water to four patients with gastric ulcer before and after meals. A month later there was a subjective improvement with progressive disappearance of the symptoms, gain of appetite and sometimes of weight. Despite these improvements, however, the gastric hyperchlorhydria persisted or was increased. Thus, these clinical results cannot be attributed to a modification of the gastric secretion nor to the mild antispastic action of the juice. They are ascribed to the desoxycorticosterone acetate-like activity of this juice that has been described by other authors.

Hypertrichosis in Tuberculous Meningitis.—Hypertrichosis occurs in a high percentage of cases of tuberculous meningitis in the course of antibiotic therapy. It is more frequent in children between the ages of 2 and 5 years and in young adults than in patients of other ages. The condition develops within the first three months of antibiotic therapy, lasts three months to one year, and disappears with the clinical improvement of the patient. Its type, diffusion, and location depend on the acuteness of the sympathetic disorders associated with the tuberculous meningitis. The author reports two cases, one in a child 5 years old and another in a girl 17 years old. Tuberculous meningitis followed a favorable course due to administration of large doses of isoniazid by the intraspinal and oral routes. Marked hypertrichosis of the face and lower limbs appeared early in the course of the antibiotic therapy and has persisted to the present after clinical cure of the patients. The author directs attention to the following facts: (1) disorders of hair growth are reactions of the sympathetic nervous system to spinal paralysis, multiple sclerosis, and tuberculous internal hydrocephalus, all of which have been reported in the literature and (2) antibiotic therapy in tuberculous diseases without meningitis, as well as in nontuberculous meningitis and nontuberculous internal hydrocephalus is not followed by hypertrichosis. He states that hypertrichosis in the course of antibiotic therapy of tuberculous meningitis is an inflammatory reaction with irritation of the diencephalohypophysial segment due to the contact of the nervous tissues with toxins of tubercle bacilli in the exudates of meningoencephalitis. The reaction elicits a response of the corticoadrenal system that results in the abnormal growth of hair.

Sympathectomy in Causalgia.—Causalgia in 48 patients treated in various peripheral nerve injury centers in Great Britain resulted in all cases from an incomplete lesion of one or more nerve trunks. The pain usually had a burning quality, was situated in the hand or foot, and was aggravated by physical and emotional stimuli. Trophic and vascular changes, though variable, were a striking feature of the condition. Pain usually began within a few hours after the occurrence of the wound and often increased slowly in severity over the first few days. Slow but steady improvement was sometimes noted after a period varying from a few months to a year or more, although for several years many patients still complained of twinges of pain when they were excited or during hot weather. Multiple nerve injuries were common, and the pain was often associated with more than one nerve. All the injuries were caused by bomb or shell splinters or high velocity missiles, and in all but two cases they were at or above the level of the knee or elbow. The clinical features of causalgia and its satisfactory response to sympathectomy can be explained by the establishment of an artificial synapse between the efferent sympathetic and the afferent sensory fibers as a result of the nerve injury. Pain arising from the disturbance in conduction will persist until effective insulation of the nerve fibers is restored or the efferent impulses in the sympathetic fibers are abolished by sympathectomy. Pain in the upper limb was always associated with an incomplete lesion of the lower trunk or medial cord of the brachial plexus or of the median nerve; when the lower limb was affected, there was an incomplete lesion of the medial popliteal division of the sciatic, the medial popliteal, or the posterior tibial nerve. These nerves carry most of the sympathetic fibers to the hand or foot. Prompt treatment by sympathectomy (preferably preganglionic), which gives marked relief in most cases, is essential to prevent the crippling deformities consequent to prolonged voluntary immobilization of the painful limb.

Synovectomy and Curettage in Tuberculosis of Joints.—The main object of operations on tuberculous bones or joints is to heal the local lesion. The tuberculous infection falls most heavily on parts of the joint where there are reticuloendothelial cells capable of trapping the tubercle bacilli: these reticuloendothelial cells are found at the ends of long bones and in synovial membranes. Free vascular communication also exists between the synovial membrane, capsule, and epiphyses so that there is usually concomitant infection of the synovial membrane and the ends of the long bones. Removal of synovial membrane is followed by rapid regeneration; consequently, partial synovectomy accompanied by antibiotic treatment affords an opportunity for fresh and healthy synovial tissue to be developed, along with fresh blood vessels that will bring the antibiotic into the diseased area. Partial synovectomy, partial capsulectomy, and curettage of necrotic foci in the bone when present, combined with careful constitutional treatment in an open-air country hospital, gave successful results in 53 of a series of 62 patients with tuberculous disease of the spine, hip, or knee. Unstable ankylosis, often noted in tuberculosis of the spine, is most frequent when the disease is in the mid and lower thoracic regions. It is often followed by deformity, reactivation of the disease, and paraplegia, especially when perispinal abscesses or granulomas are present. The combined constitutional, antibiotic, and operative treatment was helpful in securing stable ankylosis without postoperative vertebral destruction in patients presenting these features. Restoration of good function with preservation of the joint can usually be secured in patients with involvement of the hip or knee if the treatment is started in time.

Late Results of Treatment of Congenital Dislocation of Hip.—Of 889 patients with congenital dislocation of the hip treated within the first half of the century, 264 could be traced and the present state be assessed. Of the 264 patients, 155 had been treated by closed reduction; 108 of these had unilateral and 47 had bilateral dislocations. In no less than four-fifths of the patients with one hip treated by closed reduction before the age of 3 and in two-thirds of those with both hips treated, the results were satisfatcory. In patients between the ages of 3 and 7 years the unilateral cases still gave almost equally good results, but there was a rapid falling off in the ratio of successes in the bilateral cases. Nine hips were treated in six patients by immediate open reduction and the results were only moderate. Secondary operative procedures following manipulative reduction and plaster fixation were employed in 23 patients with 26 dislocated hips, and satisfactory results were obtained in 11 hips. The shelf operation was the most satisfactory procedure, especially when performed within two years from the initiation of the treatment. There were 38 patients in whom deterioration occurred some considerable time after closed reduction, the average interval between the initial treatment and the operation designed to relieve the disability being about 12 years. The effectiveness of these interventions as a whole was not remarkable; the secondary operation gave satisfaction in a little more than one-third of the cases. No reduction was attempted on account of advanced age in 15 patients, and late operation was worth the attempt in only 7. Of 27 patients with completely neglected dislocation who had not received any kind of treatment, 15 in whom function was good were able to lead a moderately active life. Results of the various operations employed were as follows: Of 20 open reductions only 4 were satisfactory; the shelf operation gave encouraging results in about two-thirds of the 36 hips so treated and the operation was effective in some children aged over 5. The notion must be abandoned that this is the upper age limit. Only four of nine rotation osteotomies were effective. Anteversion of the femoral neck as a cause of instability of the reduced hip is by no means negligible. The effective life of the successfully treated hip is the most important consideration. A good result is likely to last until some time between the 25th and 30th years. The survivors continued in fair comfort into middle life. Osteoarthritis occurred in half of the cases, but disability was limited to rather more than half of this number. Pain was a significant complaint in rather more than one-third of all patients reexamined, but sometimes occurred in the absence of a degenerative arthritis.

Progressive Joint Disorders Caused by Insensitivity to Pain.—Changes identical with those of Charcot's joints (neurogenic arthropathy) in the knee, hip and spine occurred in a 27-year-old woman who had shown from birth a consistent lack of appreciation of pain. Except for loss of pain sensation she had no other defect in her nervous functions until the spinal lesion itself produced a paraplegia. It seems probable that the changes in the patient's joints were due solely to the lack of protection usually given by the sensation of pain, though some recent authors have ignored loss of pain sensation as an important factor in the cause of neuropathic joint disease.

Psychological Concomitants of Cortisone and Corticotropin Therapy.—Rees studied the psychological changes in 40 patients receiving 50 courses of treatment with corticotropin or cortisone. Disorders found in these patients included asthma, bronchitis, arthritis, Simmond's disease, anorexia nervosa, depressive states, schizophrenia, Addison's disease, angioneurotic edema, Felty's syndrome, and anaphylactoid purpura. Each patient was observed by a team consisting of a physician, an allergist, a pediatrician, a pathologist, and a psychiatrist. The following tests were carried out: weight, water balance, eosinophil counts, blood electrolytes, electrocardiographs, daily blood pressure readings. A psychiatric history and clinical assessment was carried out. Ratings of behavior, mood, tension, awareness, and sociability were made before, during, and after treatment. During the first week, the patient was given injections of isotonic sodium chloride solution; all tests and clinical assessments were carried out during that week. No significant changes occurred during the period of inert injections; this indicates that the possible suggestive effect of the procedure was not important. No significant changes in mental state occurred in 21 of the patients, but in 19 changes varied from an increased feeling of well-being to marked restlessness, excitement, and irritability. In one-third of the patients showing increased well-being or euphoria, the change was attributable to relief of disability or symptoms. In the remaining two-thirds, increased well-being or euphoria developed before or independently of any relief of symptoms. In the early stages of treatment, elation and euphoria free from undesirable tension was found. If large doses or prolonged treatment was necessary, increased irritability and restlessness tended to develop. In some patients, particularly in those with asthma or rheumatoid arthritis, euphoria was less in second or subsequent courses of treatment. A slight improvement in well-being and appetite occurred in some patients with involutional or senile depressive states while they were treated with corticotropin, but there was no significant improvement in the depression. All patients subsequently recovered with electroconvulsive therapy. This suggests that the beneficial therapeutic effects of electroconvulsive therapy are not dependent on stimulating an increased endogenous release of corticotropin. The author believes that the absence of severe psychiatric reactions is due to the fact that the regimen employed prevented deviation in the patient's internal environment, particularly disturbances in the water and electrolyte balance. This is achieved by low salt diet, high potassium intake, and adjustment of drug dosages.

Lupus Erythematosus and Cortisone and Corticotropin.—Cortisone and corticotropin prolong the course of lupus erythematosus and thereby convert acute cases (those causing death within three months after the onset of systemic symptoms) and subacute cases (in which death occurs within one year) into chronic conditions. There is increasing evidence to show that the chronic discoid and systemic varieties of lupus erythematosus are closely related. Chronic discoid lupus erythematosus, which is not accompanied by constitutional disturbances, may be described as localized, if confined to the face and ears, or generalized, if it also involves the trunk and limbs. Systemic lupus erythematosus—acute, subacute, or chronic—is characterized by widespread collagen tissue damage, which affects particularly the vascular system and the serous and synovial membranes. Systemic lupus erythematosus may develop in patients with chronic discoid lesions, but the incidence of transition is low. Excessive exposure to natural or artificial sunlight and, possibly, previous treatment with the sulfonamides are the only factors said to produce the change to systemic involvement, which cannot be predicted. The reverse transformation of systemic to chronic discoid disease may also occur spontaneously. The unpredictable remissions characteristic of lupus erythematosus make accurate prognosis and the evaluation of therapy difficult. The more acute the systemic disease, the shorter, as a rule, is the life expectancy and the less likely are remissions. Cortisone and corticotropin were used by the authors in treating 16 patients, 7 of whom had frank systemic involvement. The initial treatment consisted of 25 mg. of corticotropin given intramuscularly at six hour intervals or 25 mg. of cortisone given orally four times a day. The patients were given a low salt, high potassium diet, with additional potassium chloride orally. The doses of corticotropin or cortisone were reduced at intervals of from five to seven days provided good progress was being maintained. No deaths have occurred, and all but one of the patients are being maintained on cortisone given orally in divided doses of from 37.5 to 75 mg. daily. The other patient, whose response to therapy has been excellent although she was acutely ill, receives a weekly maintenance dose of 10. I. U. of corticotropin gel. Results were best in the four patients with the most active systemic disease; all felt better within a few hours after treatment was started. No severe complications were caused by the hormone therapy in these patients, and the gratifying response secured indicates that the use of corticotropin or cortisone is fully justified in all but very mild cases of lupus erythematosus.

Pain in Chronic Gastric Ulcer.—Gastric ulcers removed from 22 patients by partial gastrectomy were studied macroscopically, and 650 histological sections were examined microscopically. Results revealed that the nerves in chronic gastric ulcer form two main groups, those of the ulcer edge and those of the gap. The nerves of the edge are the divided ends of the submucous and myogastric plexuses. They are the only constant group. They are enclosed within fused anatomic layers and are usually covered by the thickened mucosa and submucosa. They are end-bulbs, akin to those observed in an amputation stump. The nerves of the gap are absent when the ulcer is on the anterior or posterior wall and penetration is complete. They are the nerves of the mesentery when the ulcer is on the lesser curvature and penetration is complete. They are embedded not in anatomic layers but in the layers of Askanazy. Their destruction is gradual (unlike the end-bulbs of the edge) and completed in the granulation layer. They are separated from the gastric contents by the three inner layers of Askanazy and by the blood circulating in the granulation tissue. These layers are impermeable to gastric acid and insensitive to caustics, including hydrochloric acid. The question of which causes pain, the floor or the edge of ulcer, that is between acid and inflammation, is decided by microscopic study. There are no nerves in the floor of som painful ulcers but always many in the edge. The part fro which pain arises is "the visible palpable lesion" (the ulc itself in its full thickness) rather than the diffusely inflam mucosa. Seasonal variations in pain and pain exacerbatio before hemorrhage or perforation are due to acute exacerb tions of the chronic inflammation. Pain fluctuations during t day are brought about by hemodynamic factors, alteratio in volume, pressure, and velocity of blood flow in the painf tissue. Meat fibers may remain undigested for days in t floor of a gastric ulcer. Motor activity, including spasm, not the primary cause of ulcer pain, but, if excessive, it m cause pain secondarily by squeezing tender tissue. Acid is n the primary cause of ulcer pain, but if strong enough m cause the stomach to squeeze tender tissue. In logical orde inflammation is then the primary, the motor disturbance t secondary, and the acid the tertiary cause of ulcer pain. T author considers the hypothesis that acid acting on ner endings in the floor of the ulcer is the primary cause of ulc pain as unscientific in that it ignores gastric pain with achlo hydria and with hypochlorhydria, the deep penetrating ulcer antrum gastritis, the exacerbation of pain before hemorrha and perforation and seasonable variations in pain. Many p tients with "ulcer pain" have no nerves in the ulcer floo some have no acid, and some even have no ulcer. The ac hypothesis contradicts the essential unity of the pain mech nism.

Myasthenia Gravis and Pregnancy.—The course of the disea during pregnancy in 14 women with myasthenia gravis i whom pregnancy had occurred after they first had myastheni symptoms was as follows: Two experienced no change i myasthenia, and one was slightly improved in the last fi months. Myasthenia progressed in four, remissions occurre in two, four patients were symptomless at onset and throug out pregnancy, and one patient, who had two pregnancie had a complete remission after deep x-ray therapy at the thir month of the first pregnancy and a relapse in the secon month of the second pregnancy, with myasthenic symptom becoming gradually worse throughout the pregnancy. Six wer delivered at the hospital. Apart from myasthenia, labors wer relatively normal and the contrast between efficient uterin contractions and general muscular weakness was pronounced The postpartum course of the 14 patients was as follows: O four patients who had been symptomless during pregnancy two had postpartum relapse and two had not. Five who ha symptoms during pregnancy had postpartum exacerbation three had gradual deterioration postpartum, and two were no changed. Of seven infants (including a pair of twins) born i the hospital and carefully examined for evidence of myastheni gravis, six were normal, but one showed definite evidence o myasthenia. It is concluded that myasthenic patients can go through pregnancy without difficulty, though there is some danger of a relapse necessitating increased doses of neostigmine during the first three months. There is no medical indication for termination of pregnancy. A normal labor ca be expected, other circumstances being normal. The greatest danger is a relapse in the postpartum period, especially during the first three weeks. For this reason it is advisable for labor to be conducted in the hospital and for the patient to be kept in hospital for three to four weeks after labor. There is a possibility that the infant will show myasthenic symptoms, most notably in the bulbar and facial muscles. This neonatal myasthenia responds to neostigmine and is likely to subside completely in two to three weeks.

Streptomycin and Isoniazid in Miliary Tuberculosis and Tuberculous Meningitis.—The postmortem findings in six patients with both miliary tuberculosis and tuberculous meningitis treated with streptomycin and isoniazid were compared with those in 48 patients with either or both of these conditions, who had not received specific chemotherapy or had been given streptomycin alone or streptomycin combined with *p*-aminosalicylic acid. Results showed that in small recent tuberculous lesions, streptomycin alone caused regression but not resolution to occur. Resolution took place after treatment with streptomycin combined with isoniazid. In larger and older lesions, after streptomycin therapy, there was regressive fibrosis. When isoniazid was also administered, there was greatly increased vascularity, absorption of caseation, diminution of epithelioid cells, and loosening of old fibrous tissue, i. e., changes towards resolution. These changes occurred even in old, densely fibrosed lesions, which were not affected by streptomycin alone. It is suggested that the difference in the effects of these drugs is due to the greater diffusibility of isoniazid and possibly to its more rapid action on tubercle bacilli. It is noted that the advantages of isoniazid are not lost by combining it with streptomycin; combined use of these two drugs is the best available means of preventing the development of resistance to either drug by the infecting organism. The miliary lesions were in no way responsible for the death in the six patients treated with streptomycin and isoniazid; on the contrary the miliary lesions were all resolving satisfactorily. It has also been reported by other workers that isoniazid prevented the development of tuberculous meningitis as a complication. In the six patients the infection had been controlled not only in the miliary, but also in the meningeal lesions in which again changes indicated partial resolution. In four patients these changes were followed by cerebral softening or convulsions due to swelling of tuberculomas. These harmful effects, for which isoniazid was partly responsible, must be considered in relation to the benefits resulting from the more thorough control of the infection. Larger clinical series will be required to assess the value of isoniazid in this condition.

Leprosy as an Etiological Factor in the Weber-Christian Syndrome.—The Weber-Christian syndrome, or relapsing febrile nonsuppurative nodular panniculitis, is a condition characterized by recurrent fever associated with the formation of single to multiple crops of tender or painless inflammatory nodules in the panniculus adiposus. Birrell says that in 1952 he observed and reported the case of a 37-year-old man of Maltese origin who had lived in Australia for two years and who presented the typical symptoms of the Weber-Christian syndrome. Shortly after the publication of this case another person from Malta was seen at the Alfred Hospital, Melbourne; there was a similar clinical and histological picture. Leprosy was suggested in this second case, and Ziehl-Neelsen staining was carried out on biopsy material from one of the nodules. The finding of organisms typical of Mycobacterium leprae in this second case immediately led to a reexamination of the biopsy material from the first case and to the discovery of similar organisms in it. Birrell feels that these observations imply that the Weber-Christian syndrome is only a syndrome and not a specific disease and that leprosy may well be one of the etiological agents. A proportion of cases of the Weber-Christian syndrome may actually be cases of leprosy in a relatively early stage.

Antituberculous Vaccination in Italy.—Antituberculous vaccination with killed bacilli and results obtained with it in Italy during the last 50 years are reviewed. In 1903 Maragliano asserted that a vaccine of bacilli killed by heat had an antigen property and could induce immunity against tuberculosis. The allergy to tuberculin was, however, weak and short-lasting. A vaccine of bacilli killed by ultraviolet rays yielded better results. But the best results were obtained 25 years ago by Petragnani with a vaccine of tubercle bacilli killed by formaldehyde and stabilized through a process that reduced their virulence but preserved their morphological and chemical characteristics. Petragnani's was a great contribution to the problem of antituberculous vaccination. But he should not have called this vaccine "anatuberculin" because for a long time, especially in countries other than Italy, "Petragnani's anatuberculin" was thought to be a particular type of tuberculin. Had he used the term "tuberculous formaldehyde vaccine," many misunderstandings would have been avoided and his contribution would have been appreciated earlier. In Italy, however, vaccination with Petragnani's anatuberculin has been carried out on a wide scale. Most of the work in this field has been done by Salvioli, who after many experiments introduced the method of injecting the vaccine intradermally by four simultaneous injections arranged quadrilaterally on the forearm. A constant and long-lasting allergy to tuberculin was obtained and the mortality for tuberculosis was decreased among the vaccinated persons. The clinical tuberculous manifestations were also less severe in children in whom tuberculosis developed after they had been vaccinated. But an intense local reaction to the vaccination with formation of cold abscesses and permanent conspicuous scars after healing were pronounced side-effects. Multiple puncture vaccination was then introduced in an attempt to minimize the local reaction. It gave good results in persons older than six years but failed in infants. Vaccination with killed BCG bacilli was also attempted in the meantime, but the allergic state obtained was inferior to that produced by living BCG bacilli. Therefore studies were resumed on Petragnani's anatuberculin. In 1950 Salvioli combined anatuberculin with hyaluronidase. The enzyme potentiated the activity of the killed bacilli. The allergy became manifest two to three months after the vaccination. It was present in 95% after one year, and it became more pronounced as time passed. Local reactions were less severe, possibly because the bacilli were mobilized by the enzyme and produced granulomas of the tuberculous type in the satellite lymph nodes. Results with "Salvioli's diffusing vaccine" are promising, but studies are still in progress and a definitive evaluation of its effects is premature.

Results of Surgical Treatment in 55 Cases of Mitral Stenosis.—Bayer and associates review the results they obtained in the surgical treatment of 55 patients with mitral stenosis. The majority of the patients were in the fourth decade, and

41 were women. The majority of the patients belonged to groups 3 and 4 according to Baker's classification. There were eight fatalities, including one late one (after six months) resulting from cerebral embolism. Of the surviving patients, 3 experienced no improvement, 5 were slightly improved, 18 obtained good results, and 21 had very good results. Comparing their own results with those obtained by other surgeons, Bayer and associates find that on the whole their own results are about the same as those of other authors, although with increasing experience Bailey and associates have reduced the mortality rate to 5%. Experiences in their last 27 patients make Bayer and his collaborators hope that they too will eventually equal this low mortality rate. The surgical results are in general more favorable in cases of pure mitral stenosis without calcification than in cases in which the stenosis is complicated by mitral insufficiency and severe valvular calcification. In cases in which mitral regurgitation is considerable, correction of this defect will have to be added to the commissurotomy. In the presence of severe valvular calcification, the motility of the valvular edges, even after commissurotomy, is so slight that mitral insufficiency appears or becomes intensified. Catheterization of the right side of the heart, which permits exact determination of the pressure conditions in the pulmonary circulation in the right side of the heart and measurement of the minute volume doubtlessly is the best method for estimating the result of the operation; however, the authors feel that the decrease in pressure in the left auricle during operation, the postoperative determination of arterial oxygen saturation, and the examination of pulmonary function during rest and after measured physical exertion will also be helpful. The efficacy of mitral commissurotomy is further corroborated by changes in clinical, roentgenologic, and electrocardiographic aspects as well as in the subjective condition of the patients.

*Wilms' Tumor. F. H. van Gulik.—p. 1763.
*Neurosyphilis. A. Verjaal.—p. 1767.

Wilms' Tumor.—Embryonal tumors of the kidneys are known under many different terms, but what is generally referred to as Wilms' tumor should really be referred to as embryonal carcinoma of the kidney. After commenting on various aspects of this tumor, particularly that it practically never occurs beyond the age of puberty, the author presents the case of a man, aged 51, who had such a tumor. The growth was removed; the operative specimen weighed nearly 10 kg. and measured 40 by 30 by 20 cm. A sac containing about 4 liters of fluid and necrotic debris surrounded the tumor, which alone weighed 5,400 gm. Histological examination revealed that it was an adenosarcoma. Several months after the operation the patient stated that he felt quite well.

Neurosyphilis.—During the last 10 years, Verjaal treated 10 patients with neurosyphilis in whom the cerebrospinal fluid showed noticeable pleocytosis, increased protein content, and a pathological colloid curve. The clinical pictures varied greatly in these patients. Half of the patients were treated with arsphenamine and bismuth and the others were treated with penicillin. The results obtained with arsphenamine and bismuth were discouraging, in that only 6 of 14 patients were cured. The results obtained with penicillin seemed more favorable. However, in some of these cases the follow-up period has not been long enough to permit conclusions. Two patients in whom treatment with arsphenamine and bismuth failed were later cured with penicillin. On the other hand, two who failed to respond to penicillin were successfully treated with arsphenamine and bismuth. No relapse or exacerbation was ever observed after the changes in the cerebrospinal fluid had completely disappeared.

Recent Therapy in Acute Leukemia in Children (Folic Acid Antagonists and ACTH/Cortisone).—Nineteen children with acute leukemia, 13 boys and 6 girls, from 3 months to 1 years of age, have been treated at the Bergen Children's Clinic since it opened two and a half years ago. All received antibiotics and all but one, who was in forlorn condition on admission, were given repeated blood transfusions. The duration of survival after establishment of the first symptoms, Kåss reports, was about three and a half months for the eight patients not given aminopterin. It was six and a half months for the 11 who received aminopterin, nine of whom also received corticotropin and some also cortisone. After nineteen courses of treatment with aminopterin, complete remission for two and a half and three months respectively resulted in two cases. After combined aminopterin-corticotropin treatment in two patients, partial remission for three weeks followed in one instance. Thirteen courses of corticotropin and two of cortisone in eight patients resulted in three complete remissions for from three to six weeks and seven partial remissions for up to two months.

Sodium Salicylate in Children.—A group of children between the ages of 5 to 9 years were given antirheumatic therapy consisting of one intravenous injection of 1.2 gm. of sodium salicylate in a 30% solution of distilled water (4 cc.). For a second group of children of the same ages, the therapy consisted of oral administration of 0.20 gm. of sodium salicylate and 0.20 gm. of sodium bicarbonate per kilogram of body weight in 24 hours. The drugs were given in divided doses every three hours, and the therapy was continued for four days. The peripheral eosinophilia and the urinary excretion of 17-ketosteroids and 11-oxycorticosteroids were studied in all the children before and after the therapy. The number of peripheral circulating eosinophils dropped in both groups of children, and there was a constant and pronounced increase of the urinary excretion of 17-ketosteroids. The 11-oxycorticosteroid excretion was also increased. This suggests that the drug stimulated the function of the adrenal cortex and affected all the zones of the cortex. The excretion of metabolites of the androgen hormones was more pronounced in these children than in adult men during salicylate therapy. This may be ascribed to the fact that the 17-ketosteroids in the child come almost exclusively from the cortex of the adrenal gland rather than from the testicles, as in adult men. This drug, like cortisone, enhances protein catabolism and increases the uric acid excretion. It also increases the amount of interstitial fluid and subsequently the plasma volume. Pain and swelling of the joints disappear, and the erythrocyte sedimentation rate returns to normal. Salicylate therapy also exerts its action on the central nervous system (antipyretic and analgesic) and on the blood coagulation mechanism (prothrombin time).

*Possibilities and Limitations of Extemporaneous Cytodiagnosis. (Comment on 1,000 Cytological and Histological Comparisons). G. Castelain and C. Castelain.—p. 1020.

Extemporaneous Cytodiagnosis.—The results obtained by cytological study of tumor smears and impressions in 1,000 cases were compared with those obtained by histological study in the same cases. Scarcity or lack of nucleated elements prevented interpretation of the smears in 10 cases, while in 3 others there was disagreement between the results. Two of these showed evidences of malignant characteristics in the smears but not in the histological specimens. Careful observation and trained judgment are essential to correct evaluation of cell characteristics; although isolated neoplastic cells are sometimes obviously abnormal, they may at other times show very few structural irregularities. Smears and impressions can often be interpreted more easily, because of the number of cells shown and the ease with which they can be compared. Anisochromia and anisonucleosis can readily be seen even with weak magnification, and, when the magnification is increased, many of the nucleocytoplasmic disturbances characteristic of malignant cells become evident. Beginning metastases in lymph nodes may be highly localized; consequently, smears should be taken from the whole of the cut surface and even in some cases from several parallel sections. Both smears and impressions should be made in each case, because neoplastic tissue, which is often more coherent than the lymphoid and reticular tissue of the lymph node, is more difficult to detach and may be absent from the impression, appearing only in the smears. The appearance and density of the cells shown in smears and impressions taken from benign tumors of the breast differ largely from those found when the tumors are malignant. Not only the earliest structural deviations in tumor cells can be recognized by this method of cytological study, but their degree of malignancy may also be appraised to some extent, giving the method prognostic as well as diagnostic value.

Physiopathological Bases of Hypothermia.—Induced hypothermia or refrigeration produced by physical means should be clearly differentiated from artificial hibernation produced by the use of drugs. The authors believe that massive and prolonged administration of the drugs contained in the mixtures employed to secure artificial hibernation may be injurious and that their effect cannot be adequately controlled; consequently, they present only the results of their studies on hypothermia produced by cold. The critical temperature below which life is impossible depends on factors such as the species of the animal exposed to the cold, the age, weight, and condition of the subject, the speed with which refrigeration takes place, and the marked individual variations in neurovegetative response to cold. Experiments with guinea pigs show that tolerance for hypothermia is better when the chilling and subsequent reheating are carried out quickly than when they are induced gradually. Functional paralysis of the neurovegetative system and suppression of consciousness are secured by administration of a ganglion-blocking agent (methonium salts) and an antihistamine. Blocking of the neurovegetative system makes it possible to induce refrigeration more quickly and with less danger because it lessens the body's resistance to cold. Rapid restoration of the temperature to normal may be facilitated by parenteral administration of cortisone or corticotropin in varying doses. Overdosage may be dangerous because it may result in adrenocortical inhibition and failure to respond to stimulation. Hypothermia induced by this method facilitates operations on the heart. Benefits obtained from its use in connection with the authors' artificial heart-lung apparatus for extracorporal circulation in dogs subjected to cardiac interventions were especially encouraging. Hypothermia induced by the authors' method was used in treating 33 patients with congenital malformations of the heart and great vessels and 16 patients requiring neurosurgical procedures. Results were good in 32 of the patients in the first group and in 14 of those in the second. Convincing evidence of the value of hypothermia in preventing injury to the nervous system as a result of reduced circulation was provided when circulation was restored without symptoms of cerebral damage after cardiac arrest of 10 minutes' duration in a child undergoing valvulotomy for congenital stenosis affecting the pulmonary artery.

Serology of Toxoplasmosis.—Toxoplasma neutralization tests on rabbits, Sabin-Feldman's dye tests, and complement fixation tests were performed on a large number of serums from patients with established and suspected toxoplasmosis and serums from control persons. Results showed that the neutralization test on rabbits is too sensitive for the examination of serums from patients with suspected toxoplasmosis. A quantitative picture of the antibodies in the serum can be obtained by the Sabin-Feldman's dye test provided that in addition the complement fixation test is performed. Results from the dye test may be positive within a few days after the infection with Toxoplasma and titers may remain high for years, while results from the complement fixation test remain negative during the acute phase of the disease, turning to positive after several weeks and becoming negative again after several months. It is therefore advisable to repeat the tests after two to four weeks. Positive results from the repeated tests will be of particular diagnostic significance. The infection with Toxoplasma can be considered as established only if on repeated examination the high dye test titer is even higher or if the high dye test titer is unchanged but the result of the complement fixation test has turned from negative to positive. In any case, clinical manifestations and serologic findings should be interpreted simultaneously.

Treatment of Hypophyseal Myxedema. P. A. Bastenie.—p. 2454.

Kinetic Conception of Adrenocortical Insufficiency.—The adrenal cortical tissue may be almost completely destroyed in extreme cases of Addison's disease. The destruction of the tissue sometimes takes place rapidly; compensatory mechanisms cannot become operative, and the clinical course is fulminating, without any evident pigmentation. Transitional forms, on the other hand, may be characterized by zones of adenomatous hyperplasia appearing side by side with areas of cellular atrophy. Changes affecting the adrenal cortex apparently set in motion the normal regulatory mechanism of the adrenocortical tissue. This results in increased secretion of the corticotropic hormone. The hyperplasia produced by this hypophyseal reaction, of which one of the most obvious signs is pigmentation, compensates for the parenchymal deficiency, delaying the appearance of peripheral manifestations of adrenal insufficiency. Adrenocortical exhaustion ultimately occurs, however, and death ensues. Recognition of the numerous, more or less effectively compensated, transitional forms of adrenocortical insufficiency will make it possible to reestablish a satisfactory balance by adequate treatment. Small doses of cortisone will not only furnish the steroids essential to life and normal activity but will also halt the overstimulation that is largely responsible for the progressive destruction of the remaining adrenal tissue. The existence of mild forms of Addison's disease, the dissociation between certain clinical and biological signs, the variable test responses of certain patients with Addison's disease, and the prolonged course of the atrophic forms of the condition, with their exacerbations ending in brutal decompensation and death, can all be explained by this kinetic conception of adrenocortical insufficiency.

Attempted Homeotransplantation in Second and Third Degree Burns. W. Jung.—p. 599.

Intermittent Massive Penicillin Therapy in Surgery.—After commenting on the relative therapeutic value of water soluble and repository penicillins, von Lutzki points out that in most surgical clinics in Germany both types of penicillin are used. He also discusses serum concentrations of penicillin that are necessary to exert bacteriostatic, bacteriocidal, and bacteriolytic effects on various microorganisms. The results of animal experiments, bacteriological observations, and determinations of blood levels of penicillin seem to suggest that, instead of striving to constantly maintain a bacteriostatic penicillin content in the blood, it might be preferable to raise the concentration of penicillin in the blood at intervals to bactericidal or bacteriolytic levels. By administering "massive doses of penicillin intermittently" (shock or thrust therapy), the pathogenic organisms could be combatted decisively during their different developmental phases, particularly during division and growth. At the author's clinic this form of intermittent massive penicillin therapy has been in use since 1949. In 1950 observations were reported in 400 patients in whom this form of penicillin therapy had been used, and since then 900 more patients have been treated in this way. These 1,300 patients included many with severe bacterial infections, such as ulcerations, abscesses, furuncles, carbuncles, thrombophlebitis, osteomyelitis, erysipelas, mastitis, and bronchopneumonia, and also hundreds of cases in which operations on abdominal or thoracic organs had to be performed in the presence of ba terial contamination. Observations on these patients convinc the author that the intermittent administration of massi doses of water soluble penicillin is very effective. Doses 400,000 I. U. are generally given twice a day. Such doses water soluble penicillin produce concentrations of 20 to I. U. per cubic centimeter of serum from 15 to 30 minut after the injection. This intermittent administration of massi doses of water soluble penicillin combines the ease of pository penicillin therapy with the therapeutic reliability short interval (every three hours) injections of penicillin; fact, in therapeutic efficacy it often surpasses both metho The bactericidal and bacteriolytic effect of penicillin is ful exploited with this form of therapy, and as a result the ther peutic spectrum of penicillin is extended and it becomes effe tive against highly resistant microorganisms. The emergen of resistant strains is avoided or reduced. Local tolerance high concentrations of water soluble penicillin is good.

78:689-736 (No. 17) 1953. Partial Index

*Advantages and Disadvantages of Küntscher's Method of Nailing in General Hospital. E. Weyand.—p. 689.

Simplifying Nailing of the Neck of the Femur. U. Glöckner.—p. 700.

Tumor-Like Endometriosis of the Thigh. A. Schulz and G. Zehr —p. 708.

Aspects of Hemangiomas of the Knee Joint. G. Bertele.—p. 711.

Experiences in 500 Intra-Arterial Injections. H.-J. Paulus.—p. 718.

Küntscher's Method of Nailing: Advantages and Disadvan tages.—Weyand says that the first enthusiasm for Küntscher method of nailing has given way to a more reserved attitud At his own clinic nailing was employed in 67 fractures tubular bones in 64 patients, that is, in a relatively sma proportion of fracture cases seen at a general hospital. Th number included 20 simple fractures, 44 compound fracture and 3 pseudarthroses. Compound fractures were usually treat by medullary nailing, provided there were no contraindic tions, such as cerebral concussion, shock, or unsuitable loc tion of the fracture. In closed fractures, however, naili was restricted. Except for two cases, nailing was done the open method, since, as a rule, the wound had to be treat anyway and the introduction of the nail is much simplifi in this way. Furthermore, shock and fat embolism can avoided. The author usually employed sulfonamides or pe cillin. Although secondary healing has not been reduced sin penicillin has been in use, suppurations of the soft parts, well as of the bones, has been considerably reduced. In ord to avoid complications caused by the nail itself the autho always used somewhat thinner nails whenever there was a doubt. For this reason, calcium sulfate (Plaster-of-Paris) cas or splints were used in addition to nailing, except in cas of fracture of the femur, in which the nail in itself insur adequate stability. Hospitalization generally was 8 weeks f fractures of the femur, 9 weeks for fractures of the leg belo the knee (7 weeks in case of the humerus), and 12 weeks f fractures of the arm below the elbow. A definite reductio in the time of hospitalization, in comparison with forme treatments, was achieved only in the case of fracture of th femur. Good position and its preservation as well as favo able functional results were a decided advantage in all frac tures treated by means of nailing. Despite fixation by bandage active movements could be encouraged during the perioc when the cast was changed, and still there was no need fo concern about proper position or pseudarthrosis. Callus fo mation was good in fractures of the femur and of the humeru but in cases of fractures below the knee or below the elbo it was less than normal in about 50% of the cases. Interna splinting seemed to be a particular advantage in cases i which the soft parts of the arm had been severely lacerated In the three cases of pseudarthrosis, adequate rigidity wa obtained in a relatively short time after nailing. The autho found nailing particularly helpful in simple and compound fractures of the femur, also in fractures of the leg below the knee, provided the fracture was about in the middle, and in pseudarthrosis of the lower leg. In fractures of the upper and lower arm he recommends nailing only when surgical intervention is necessary or when internal fixation seems advantageous on account of severe destruction of the soft parts.

BOOK REVIEWS

The Surgery of Infancy and Childhood: Its Principles and Techniques. By Robert E. Gross, M.D., D.Sc., William E. Ladd Professor of Children's Surgery, Harvard Medical School, Boston. Cloth. $16. Pp. 1000, with 1488 illustrations, drawings by Etta Piotti. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, 1953.

When "Abdominal Surgery of Infancy and Childhood" by Ladd and Gross appeared in 1936, it was immediately accepted as authoritative and, indeed, the only current American text on the subject. Although reprinted in 1941 and 1947, it was never revised. As a result, the present volume has been long and eagerly awaited. Although written by Gross alone, this monograph follows the earlier work closely but covers a wider field. Although the title has been changed from "Abdominal Surgery" to "The Surgery of Infancy and Childhood," there is nothing on orthopedic surgery, neurosurgery, or otolaryngology, and, though there is a short chapter on wringer injuries of the arm, there is nothing on fractures or acute osteomyelitis. On the other hand, urology is covered, including the plastic correction of hypospadius, and there is a short chapter on gynecologic disorders in the female infant and child. Harelip and cleft palate are not included nor is the care of thermal burns. Nearly 30% of the text is devoted to thoracic surgery, a field to which the author himself has made notable contributions. Because the present volume adds only this subject to the original abdominal surgery of Ladd and Gross, a more accurate title would have been "The Abdominal and Thoracic Surgery of Infancy and Childhood." The book should be valuable for the detailed records of the author's experiences in the Children's Hospital at Boston. The improvements made in the past decade are clearly depicted. The illustrations are excellent. Most of the step-by-step drawings of operation technique, however, are interesting enough to those well trained in surgery but are obviously inadequate for the use of those who are not and who might be tempted to operate on the basis of a series of well-executed and simple diagrams. For example, a herniotomy in an infant may look easy from such visual instructions, yet, unless the operator is sufficiently trained in the handling of fragile, easily damaged tissues, he may find himself performing an inadequate and perhaps harmful operation. This is an important criticism, because the author clearly states that even the smallest babies can be operated on with safety and satisfaction if competent anesthetists are available and if the surgeon has experience in the field and is willing to make a delicate dissection and a careful handling of the parts. This conclusion, with which most well-trained surgeons and pediatricians would agree, is a departure from the previous policy of using a yarn truss until the child is one or two years old. This lesson still needs to be learned and widely adopted wherever adequate surgical treatment is available. Over 5,000 deaths a year in the continental United States are still listed under hernia. Most of these could be prevented by early herniotomy.

The chapters devoted to preoperative and postoperative care and anesthesia and to surgery in premature infants are especially noteworthy. An excellent though short page is devoted to psychogenic factors, so often neglected. An important point in the water balance of infants is emphasized and should be more widely known, namely the tendency toward the administration of too much fluid parenterally. It is made clear that the water requirements for maintenance in the absence of deficits in the premature and newborn infant should be closer to 60 ml. per kilogram of body weight than the usually recommended 150 ml. and that serious complications may follow the use of the latter amount, especially if the solution contains too much salt.

The sections on intestinal obstruction, including a new chapter on meconium ileus, should be valuable and illuminating. The fact that only one death occurred in 345 cases of peritonitis from perforated appendicitis offers ample justification for the plan of early operation following adequate preparation as used in all of these patients. In performing appendectomy for acute appendicitis, the permissible error is often discussed in terms of the proportion of such cases in which a normal appendix is found. Although the experience in this large clinic in this regard would have been of great interest, it is not stated.

The chapter on congenital malformations of the anus and rectum is excellent and complete except for the omission of treatment of rectovesical or rectovaginal fistulas that persist after the imperforate anus alone has been treated at birth by a perineal procedure. The combined abdominoperineal procedure performed in the newborn for a high-lying rectal pouch is well described and recommended but referred to as a "major undertaking." As a word of warning to the untrained surgeon, this would certainly be a valuable comment, but for the adequately trained surgeon, it might be unnecessarily discouraging. The chapter on congenital megacolon is unusually informative and includes a full and excellent description of Swenson's work. In the chapter on Meckel's diverticulum, perforation is mentioned and illustrated, but general peritonitis as its sequel is not discussed under either pathology or clinical manifestations. Prolapse of the rectum, though briefly discussed in the earlier book, is omitted. Malrotation, which is always difficult to describe, is well presented and illustrated in a separate chapter. Ladd's operation is described therein as a freeing and transferring of the cecum and ascending colon to the left, but no mention is made of another and perhaps commoner type of malrotation also described by Ladd, in which the cecum and terminal ileum are freed and transferred to the right.

This monograph in general is a source of useful, clearly presented information that not only will please the old readers of Ladd and Gross but undoubtedly will draw many new ones. It is an outstanding and significant addition to both surgical and pediatric literature.

Diseases of Muscle: A Study in Pathology. By Raymond D. Adams, M.A., M.D., Associate Clinical Professor of Neurology, Harvard Medical School, Boston, D. Denny-Brown, M.D., D.Phil., F.R.C.P., James Jackson Putnam Professor of Neurology, Harvard Medical School, and Carl M. Pearson, M.D. Cloth. $16. Pp. 556, with 347 illustrations. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1953.

This monograph, according to the authors, was "originally planned as a syllabus of the pathologic changes in skeletal muscle, to aid in the teaching of graduate students of neurology and pathology." As the material to be included accumulated, they decided to undertake a systematic review of the general subject of diseases of skeletal muscle from the viewpoints of embryology, anatomy, physiology, and pathology. In doing so, they had the active cooperation of pathologists, anatomists, and clinicians in the Boston area. The result is a beautifully printed and illustrated book.

The book is divided into three parts. Part 1 deals with the nature of skeletal muscle from the standpoint of embryology, anatomy, histology, chemistry, and physiology, with particular reference to muscular contraction and the relationship of the latter to neuronal activity. Part 2 is concerned with the pathological reactions of skeletal muscle, as for example, denervation atrophy, atrophy of disuse, reaction to injury, regeneration, contracture, etc. Both experimental and clinical material is included. Part 3 deals with the pathological changes relating to diseases of muscle. Here a large number of muscular diseases is discussed with the aid of many excellent photomicrographs. This book will be of particular interest and value to internists, neurologists, surgeons, and pathologists. An excellent index and hundreds of references will make it

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

helpful to all who may be interested in muscular disease. It is the first monograph of its kind in English, and, by its publication, the authors and publishers have made a noteworthy contribution to this phase of American medicine.

Operative Gynecology. By Richard W. TeLinde, M.D., Professor of Gynecology, Johns Hopkins University, Baltimore. Second edition. Cloth. $20. Pp. 902, with 416 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.S.2; 2083 Guy St., Montreal, 1953.

Dr. TeLinde has prepared a valuable treatise on gynecologic surgery. The subject is handled in a clear, convincing, and unbiased manner. Sufficient detail is included to make the book valuable from the standpoint of the occasional gynecologic operator, and, at the same time, hints and suggestions valuable to men with considerable gynecologic experience and training are given. Preoperative care, anesthesia, postoperative care, and complications are very well treated, and their importance to the ultimate success of the procedures is emphasized. The relationship of associated urological conditions, such as vesicovaginal and urethrovaginal fistulas and operative injury of the ureters, are carefully described, together with birth injury and prolapse of the vagina following supercervical as well as total hysterectomy. Malignant tumors of the uterus, their cytological diagnosis by the Papanicolaou smear method, and carcinoma in situ are thoroughly described.

There is an excellent discussion of endometriosis, including the theories of its origin, and of adenomyosis. Gonorrhea is very well handled, and the conservative management of this disease is stressed. The newer aspects of the management of tuberculosis of the female generative organs and the application of the antibiotics and *p*-aminosalicylic acid to these infections are described. Culdoscopy is discussed and its advantages and disadvantages pointed out on the basis of the author's personal experience with the procedure. Ovarian tumors are well covered, and the practical difficulties of detection, differential diagnosis, and management are clearly pointed out. Such associated conditions, not strictly gynecologic but that may be encountered and must be treated by the gynecologist, as retroperitoneal tumors, hernias, diastasis recti, appendicitis, injury to loops of intestine, regional ileitis, and Meckel's diverticulum are discussed. The final chapter, on estrogen therapy of the menopause, could have been omitted from a book on operative gynecology but was probably included for the sake of completeness.

The book is printed on good paper with very legible type. The illustrations generally are clear and anatomically correct. They are done for the most part by excellent artists, for example, Max Brödel. Some of the photomicrographs might have been more valuable had they been in color. This book should be valuable in the library of the gynecologist, the general surgeon, the general practitioner who is occasionally faced with gynecologic problems, and for students, interns, and residents.

The Fourth Mental Measurements Yearbook. Edited by Oscar Krisen Buros. Cloth. $18. Pp. 1163. Gryphon Press, 220 Montgomery St., Highland Park, New Jersey, 1953.

While technically called a yearbook, this volume actually covers the period from 1948 to 1951. This is a comprehensive and critical review of various psychological treatises on mental measurements, and it reviews 793 tests by 308 reviewers. In addition to this, 429 books on measurements in related fields are reviewed. Over half of the tests have been reviewed by one or more expert reviewers. The tests reviewed are divided into the following categories: achievement, batteries, character and personality, English, fine arts, foreign languages, intelligence, mathematics, reading, science, sensory-motor, social studies, vocations, and miscellaneous. Under the large miscellaneous category are considered agriculture, business education, computational and scoring devices, etiquette, handwriting, health, home economics, industrial arts, philosophy, psychology, record and report forms, religious education, safety education, and testing programs.

The value of this book lies in its critical evaluation of most of the psychological tests in common use and even those in relatively uncommon use. The critical evaluations by experts in this field are evident throughout the book; for example, Dr. Elton Hocking, in evaluating French I and II achievement examinations in secondary schools, states this test is not recommended for any circumstance and then goes on to explain that it is not recommended because of faulty construction in both French and English and poor layout typography and spelling. Another example of the carefully documented opinions is brought out, for example, by Jerome E. Doppelt in discussing the immediate test. It is a quick verbal intelligence test. He points out that in the determination of M.A. or I.Q. much is dependent on the proper allocation of words to mental years and therefore the procedure used to assign words is of considerable importance. Dr. Doppelt points out that the manual under consideration is woefully inadequate on this point. The matters of control studies are looked into by most of the reviewers. This is a reference book of interest to all investigators or practitioners whose fields touch on psychological testing. It is impossible to evaluate completely and critically a book of this magnitude.

The Book of Health: A Medical Encyclopedia for Everyone. Compiled and edited by Randolph Lee Clark, Jr., B.S., M.D., M.Sc., Director and Surgeon-in-Chief, University of Texas, Galveston, and Russell W. Cumley, B.A., M.A., Ph.D., Director of Publications, University of Texas. Second edition. Cloth. $10. Pp. 768, with some 1400 illustrations. Elsevier Press, Inc., 402 Lovett Blvd., Houston 6; 155 E. 82nd St., New York 28; 118 Spuistraat, Amsterdam C, Netherlands, 1953.

One of the most interesting and well-prepared books on health for the laity is this new addition to the field. The advisory board and the editorial board contain names known to almost everyone, and the book offers the culmination of what must have been a wealth of painstaking work. The book is beautifully prepared, is amply illustrated, is written in an understandable and straightforward manner, and unquestionably provides useful information in the way that will appeal to its users. It is not intended to be a guide for self-diagnosis and treatment but rather is a collection of information for those who are curious about health and disease. It contains some unusual information, for example, what a donor may do with his eyes after death. There are many pictures, such as those relating to corneal transplantation, which some might believe have no place in a book of this type, but, on the other hand, in this present day and age when the public is so curious about health matters these illustrations will do much to satisfy this curiosity. For physicians who wish to recommend a book to patients, this one will be satisfactory. As a source of answers to "how" and "why," it can be highly recommended.

Children in Play Therapy: A Key to Understanding Normal and Disturbed Emotions. By Clark E. Moustakas. Cloth. $4.50. Pp. 218, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18; 95 Farringdon St., London, E.C.4, 1953.

Playroom scenes make up most of this seven-chapter book in which actual case studies have been recorded and interpreted in some instances. Both normal children with mild difficulties and children with severe emotional problems are considered. Clues to underlying causes of the abnormal attitudes are provided in the conduct of the children, and, at the same time, guides are given to proper solution of the maladjustment. In one unusual approach, the cooperation of an entire family is given in great detail as problems of a 4-year-old daughter are resolved. This chapter contains interviews, reports of play sessions in which the mother is a participant, and interpretations and fills more than 100 pages.

Attitudes and the therapeutic process in this relatively new field are considered in the first chapter, and, in the second chapter, the significance of play therapy as a valuable mental hygiene preventive program is emphasized. Play therapy can be a satisfactory outlet at times for normal children, helping them to solve temporary home problems. This is illustrated in another chapter, in which several cases are presented and discussed. Similar presentations are utilized in the chapter dealing with disturbed children.

Parents and teachers having to cope with emotional disturbances in children will undoubtedly find this volume of considerable value as a source of insight and helpful suggestions on attitudes that may relieve difficult situations.

QUERIES AND MINOR NOTES

BLOOD TEST FOR CANCER

To the Editor:—*Is there a reliable blood test for cancer? What is the West-Hilliard test for cancer?*

Arthur L. Gaetani, M.D., Milton, Mass.

Answer.—There does not appear to be any blood test that will categorically indicate the presence of cancer. A number of serological tests have been proposed in recent years but these appear to be nonspecific and of little practical value. The West-Hilliard test was reported in *Proceedings of the Society of Experimental Biology and Medicine* (71:169, 1949). The authors described a proteolytic enzyme inhibitor in the serum of patients with a variety of pathological states including neoplastic disease. They stated that if the patient is doing poorly there is a high antichymotrypsin level, whereas this titer is reduced if clinical improvement occurs. They propose (*Cancer* 4:177, 1951) that the ratio of antichymotrypsin to antirennin may be of value in following the progress of cancer. When the antirennin level is high and the antichymotrypsin level is low, tumor growth is arrested, whereas, if the situation is reversed, the tumor is growing.

PARKINSON'S SYNDROME AND TRAUMA

To the Editor:—*Parkinson's syndrome developed in a patient about two months after he had a moderately severe concussion. Nielsen, in his book on clinical neurology, states that there is increasing belief that trauma is an important causative factor. Please discuss this opinion.*

Horace Hagen, M.D., San Luis Obispo, Calif.

Answer.—The question is not entirely clear, since "Parkinson's syndrome" is not a discrete entity. Parkinson described only the progressive degenerative form. Symptoms of lethargic encephalitis, manganese poisoning, asphyxia, and occasionally tumors may simulate but do not duplicate the degenerative "true" parkinsonism. The inquirer does not accurately quote Nielsen (Textbook of Clinical Neurology, New York, Paul B. Hoeber, 1946, p. 192), who wrote, "There is considerable evidence accumulating to indicate that the syndrome may be precipitated by trauma. It seems impossible for trauma to be the entire cause but it probably can be an exciting factor." It is true that the degenerative form may be precipitated by trauma, such as the inquirer describes, but it is assumed that the disease was latent, perhaps even present, before the concussion and that it caused the symptoms to appear sooner than they otherwise would have appeared. Aggravation of a preexisting condition is the most that can be ascribed to the trauma.

LEG CRAMPS DURING PREGNANCY

To the Editor:—*In my obstetric practice, I frequently see patients in the third trimester who have nocturnal leg cramps, although they receive adequate amounts of calcium. What therapy is indicated in these patients?*

O. J. Kirksey, M.D., Mulberry, Ark.

Answer.—Cramps in the legs during pregnancy are painful, tetanic contractions of the gastrocnemius muscle that commonly occur early in the morning and oftenest between the 24th and 36th weeks of pregnancy. They are preceded by stretching and relaxing of the calf muscles. They can be relieved in many cases by daily administration of 10 mg. (1/6 grain) of thiamine hydrochloride. During an attack, massage and/or standing on a cold floor, such as the floor of a bathroom, help. E. W. Page and E. P. Page (*Obst. & Gynec.* 1:94 [Jan.] 1953) maintain that large quantities of milk or dicalcium phosphate cause a predisposition to muscular tetany. The consumption of milk causes a fall in diffusible calcium and a rise in the inorganic phosphorus concentrations of the blood. According to Page and Page, leg cramps may be either prevented or relieved to a significant degree by *(a)* reducing the intake of milk, *(b)* using calcium salts free of phosphorus, or *(c)* adding small quantities of aluminum hydroxide gel to the diet to remove some of the dietary phosphorus from the intestinal tract. The reduction of milk and the addition of aluminum hydroxide gel to the diet relieves leg cramps by causing a rise in the ionizable calcium concentration of the blood.

ASCHHEIM-ZONDEK TEST

To the Editor:—*What conditions other than pregnancy will cause a positive result in the Friedman or Aschheim-Zondek test? I have been unable to find the answer in any of the available textbooks.*

M.D., New York.

Answer.—The Greenhill-DeLee "Textbook of Obstetrics" (ed. 10, Philadelphia, W. B. Saunders Company, 1951, page 125) says, "A positive reaction to the Aschheim-Zondek or other biologic test does not always indicate the presence of a pregnancy, a hydatidiform mole or a chorionepithelioma. Occasionally a positive reaction will be obtained in the following conditions: (1) ovarian cyst, especially a persistent corpus luteum, (2) during spontaneous or artificial menopause, (3) tuberculous salpingitis, (4) menstrual disorders, (5) during treatment with anterior pituitary preparations, (6) pelvic inflammatory disease and (7) carcinoma."

EFFECT OF ANTIHISTAMINES IN COAGULATION TIME

To the Editor:—*Is there any evidence that bleeding and coagulation times are affected by antihistamines? Is a woman more likely to bleed post partum if she has taken antihistamines in therapeutic doses prior to delivery?*

Robert G. Brown, M.D., Redwood City, Calif.

Answer.—Gerhard Zetler (*Klin. Wchnschr.* **29**:255 [April 1] 1951) says there is nothing in the literature about the effect of antihistamines on blood coagulation; therefore, he performed experiments on rabbits. He found the following changes were produced in blood coagulation time calculated in per cent of normal: histamine, -19%; antazoline (Anistine) hydrochloride, +18%; pyrilamine (Neo-Antergen) maleate, +27%; histamine plus antazoline hydrochloride, -9.4%; and histamine plus pyrilamine maleate, +7.8%. R. Fikentscher and M. Meyhoefer (*Med. Monatsschr.* 3:922, 1949) found only one case of profuse genital bleeding produced by antihistamines (case of Walther reported by R. Schubert) in the literature. Likewise, labor-like uterine contractions were produced in the premenstrual period after intravenous injections of antazoline hydrochloride in one of Walther's cases. Fikentscher and Meyhoefer report bleeding from the uterus as a side-effect of antihistamine therapy. They observed three cases within six months. There was no doubt that the bleeding was produced outside of the time of normal menstruation. In two cases, the bleeding followed one large dose of antazoline given in the midmenstrual interval. In the third patient, several doses were given before the bleeding occurred. In all the cases, the bleeding stopped when the medication was withdrawn. The authors say that antihistamines should be given with care to women who have profuse menses and, above all, to those who are pregnant. In all cases of bleeding of unknown origin, one must think of previous oral or parenteral administration of antihistamines as a possible cause.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

M. C. Shelesnyak (*Am. J. Physiol.* **170**:522, 1952) says that unpublished data (Shelesnyak and Davies) on the influence of subcutaneously administered diphenhydramine (Benadryl) hydrochloride on pregnancy suggest that, in mice treated with the drug during the approximate time of natural placentation, interference with nidation occurs, since pregnancy does not go to term. T. W. McElin and B. T. Horton (*Am. J. M. Sc.* **218**:432, 1949) studied the effects of histamine during pregnancy and said that postpartum bleeding did not occur in any of their cases. S. Lundin (*Nord. med.* **45**:436, 1951) reports a case of hemorrhagic diathesis and renal insufficiency following antihistamine medication for pruritus gestationis. The bleeding manifested itself in hematuria and cutaneous and mucosal hemorrhages and ran a course with lowered prothrombin content and prolonged coagulation time. The accompanying renal insufficiency was of lower nephron nephrosis type. The author considers the condition to have been due to a lesion of the parenchyma following the medication. The patient was restored to health.

ULCERATIVE PHARYNGITIS IN AN INFANT

To the Editor:—*A normal 3-month-old child was given his first injection of tetanus and diphtheria toxoids with pertussis vaccine combined (alum precipitated). Six days later he had anorexia, a low-grade fever, and ulcerative pharyngitis. Penicillin appeared to help and dysphagia and anorexia was speedily relieved, but the ulcers were not changed in appearance. After 10 days the ulcers appeared to be healing. At this time administration of oxytetracycline (Terramycin) for four days appeared to speed up healing of the ulcers. The patient was subjected to the second injection of the toxoids combined with the vaccine. About 8 days later, and again, within 48 hours after the injection, the mother noticed a similar pharyngeal ulceration. This time the response was as good or better to diphenhydranine (Benadryl) than it had been to penicillin during the initial flare-up. Oxytetracycline was given as well as diphenhydramine, and healing was speeded up. It has been suggested that the pertussis component was responsible for these two reactions, or that the baby harbors a herpes-like virus, the resistance to which is temporarily lowered by the injections. It has been suggested that the third injection be given guardedly in divided doses according to his reaction to each injection. An older sibling shows a definite allergic reaction of a nasal type. I shall appreciate an opinion on this unusual phenomenon and recommendations as to further immunizing procedures.* *J. R. Burnett, M.D., Effingham, Ill.*

Answer.—The administration of various antigens to infants has been blamed not only for local (cystic) and systemic (febrile) reactions, but also for proxysmal cough, convulsions, encephalopathy, and poliomyelitic paralysis of injected limbs. This is perhaps the first reported instance in which the pertussis component of tetanus and diphtheria toxoids with pertussis vaccine combined is blamed for recurrent anorexia, dysphagia, and ulcerative pharyngitis. This repeated coincidence of a hitherto unreported sequel to antigen administration makes it seem that an extraneous factor of one kind or another precipitated the localized infection of the buccal mucosa. It is conceivable that regional blanching of the pharynx due to aspirin in an infant so young might create a spot of lessened resistance. The query failed to state whether the infant's throat appeared normal when carefully inspected by the physician before the antigen was given, whether medicaments, such as aspirin (insufficiently dissolved and diluted), were given after both injections, or whether, to placate the fretful infant, the mother introduced into the infant's mouth a contaminated pacifier or nipple. In infants so young, potent antibiotics should be used only against specific bacterial infections. Splitting the final dose of the toxoids and vaccine might be tried, but it seems doubtful whether this would influence the recurrent viral pharyngitis very much. One should be certain that an injection technique is flawless (see The Journal, Aug. 1, 1953, page 1314).

PSORIATIC ARTHRITIS

To the Editor:—*I have psoriatic arthritis; the course of th arthritis follows closely the progression of the psoriasi The only effective treatment in the past has been potassiu arsenite (Fowler's) solution, which brings about an almo complete remission. I would appreciate information on th toxic effects of potassium arsenite solution and the ther peutic value of any other arsenic preparation without th toxicity of potassium arsenite solution.*

M.D., New Mexico.

Answer.—Treatment of psoriasis by means of arsenic preparations may cause remission of skin eruptions. Th improvement, however, is generally temporary. Because th disease is so long-lasting and because of the high incidence relapses, the use of arsenic-containing preparations probabl is undesirable. If one were to repeat application of arseni containing medications each time a relapse occurs, the patie would undoubtedly suffer arsenic intoxication.

Acute arsenic poisoning, as occurs in suicide attempts wi arsenic-containing substances, following accidental ingestion copper acetoarsenite (paris green) or rat poison is characteri tically accompanied by intense abdominal pain, diarrhea, an vasomotor collapse. Death may follow within a few hours sufficient amounts are taken. Chronic arsenic poisoning, occurs after prolonged administration of potassium arsenit (Fowler's) solution, is rare today. A few decades ago, however when arsenic was widely used in medicine, this type of poisoning was not infrequent. Long-continued administration o potassium arsenite solution, or the other arsenic-containin preparations described in the Pharmacopeia, may induc peripheral neuritis, paralysis, anesthesias, and neuritic pain The skin may show edema, brown pigmentation, and hype keratoses, and the latter may progress to epithelioma forma tion. Anemia of the hypochromic type, anorexia, gastric di turbances, episodes of diarrhea, perforation of the nas septum, and encephalitis may occur. Confirmation of th diagnosis of chronic arsenic poisoning is made by demon strating arsenic in the urine, stools, hair, or nail clippings.

More satisfactory and far safer than arsenic for treatme of psoriasis is the Goeckerman treatment. The procedure entirely free of hazards of toxicity. The patient is instructed t remove as many of the scales as possible by soaking an rubbing with cloths or soft brushes. Thereafter, an ointme containing crude coal tar is applied. The following formula satisfactory: crude coal tar, 16 parts; zinc oxide, 16 part starch, 125 parts; and petrolatum (Vaseline), 240 parts. Th ointment is usually applied at night. In the morning it removed by scrubbing with soap and water, and thereafte a generalized ultraviolet light treatment is given with a lam This process may be repeated daily until the eruption is unde control. Treatments should be repeated from time to tim whenever the eruption tends to reappear. For patients wit arthritis as well as psoriasis, general measures, such as ade quate rest, removal of infected foci, and attention to diet s as to provide an optimum intake of basic foods, should b encouraged. In addition, physical therapy is usually wort while, and consideration may be given to the concomitan administration of gold, cortisone, corticotropin (ACTH), an other medicaments.

EXTERNAL MEASUREMENT OF THE HEART

To the Editor:—*Where can I find a chart giving average for the cardiothoracic ratio in relation to height and weigh charts?* *Robert H. Bossert, M.D., Paso Robles, Calif.*

Answer.—It is believed that any external measurement o heart size is not accurate, although it does provide a workable scheme in some instances. Errors occur particularly in cases of mitral stenosis in which the anterior-posterior diameter is increased and in which there is encroachment on the retrocardiac space. It is also true that in persons with enlargement of the outflow tract of the heart, distortion of the cardiac silhouette may be mistaken for myocardium.

The prediction table most commonly used for the average, normal transverse diameters of the heart silhouette based on the teleoroentgenogram is the one developed by Ungerleider and Clark and reported in the *American Heart Journal* (17:92, 1939). Another table frequently used for the prediction of average, normal orthodiagraphic measurements of the transverse diameter of the heart is the one by Hodges and Eyster reported first in the *Archives of Internal Medicine* (37:711, 1926). Those tables are reproduced in the new, fifth edition of the New York Heart Association's "Nomenclature and Criteria for Diagnosis of Diseases of the Heart and Blood Vessels" available at any office of American Heart Association.

Gonzalo Esguerra Gomez of Bogotá, Colombia, published in *Radiology* (August, 1951) "The Importance of the Relation Between the Anthropometric Index and the Transverse Cardiac Diameter for Appraising the Size of the Heart." The Medical Department of the Equitable Life Assurance Society of the United States has published an interesting brochure on roentgenology of the heart.

ODOR OF CARBON TETRACHLORIDE IN DRAFTING ROOM

To the Editor:—*In the drafting room of a local engineering company, carbon tetrachloride is used to clean drawings before blueprints are made. A large bit of cotton is saturated by pouring the carbon tetrachloride from a jug; the drawings are then vigorously scrubbed with the saturated cotton. This process is repeated for varying lengths of time during each working day so that for perhaps half of each day the air in the drafting room is permeated with a strong odor of carbon tetrachloride. There are no special provisions made for ventilation. Is it necessary to have an analysis of the air in this room? Would you recommend that a special hooded, forced draft booth be used for the cleaning of these drawings with carbon tetrachloride?*

Victor T. Hudson, M.D., Mobile, Ala.

Answer.—As described, this procedure is perilous. No air analysis is required. The concentration of fumes just above the drawing being cleaned inevitably will be high. A booth with an exhaust will provide some protection, but the cleaning involves close application, so that the draftsman would be required to thrust his head into the booth. Some general room ventilation of mechanical type is in order. Methylchloroform, a less harmful agent, may be a suitable substitute for the carbon tetrachloride, but this chemical may be corrosive for some metal drafting instruments. Methylene chloride or a 50% mixture of methylene chloride and toluene may serve better. If neither of these cleaning agents is suitable, some other less dangerous substitute should be found.

RENAL CALCULI

To the Editor:—*A 40-year-old patient from India has lived in Singapore for the past 20 years, and for the past 20 years he has had kidney stones. He has pyuria but very little pain, no temperature, dysuria, hematuria, or increased urinary frequency. He has normal blood calcium and phosphorus. His urine culture shows Staphylococcus aureus hemolyticus. His heart, blood pressure, and electrocardiogram are normal. Some physicians have advised operation, but others say he should be operated on only if obstruction develops. Which advice should he take?*

M.D., New York.

Answer.—The question of operating on a patient having multiple, large renal stones that are causing no symptoms other than pyuria, frequently presents itself. There are many factors involved. If there is evidence of renal retention, surgical treatment is indicated. This would be particularly true if the patient has a horse shoe kidney. Another factor indicating surgery would be an increasing degree of renal insufficiency. No data in regard to renal function are included in the description of this case. If the blood urea is normal and the function from either half of the kidney is equal, there would not be much indication for immediate surgical interference. Renal surgery would not be advisable unless the patient is living in a community where expert renal surgery, with the aid of renal fluoroscopy at the operating table, and excellent postoperative urologic treatment were available. Before a final answer could be given, a complete urologic study would be essential. Under the circumstances, therefore, it would seem that in this case the lesion would be better left alone.

A BRUIT IN THE LEFT EAR

To the Editor:—*A white woman, 34 years old, with physical examination entirely noncontributory, developed a high-pitched bruit in the left ear when she was seven months pregnant. Now, four months after delivery, the sound continues, varying slightly with emotional circulatory changes. I have been able to hear the sound with my ear against hers. It is a very disagreeable, high-pitched bruit, synchronous with the pulse. It would be disturbing even to a sluggish mentality but is particularly so to this highly sensitive patient. Is there any treatment?*

Malcolm B. Wilcox, M.D., Kearney, Neb.

Answer.—A bruit that can be heard with the ear or by stethoscope is vascular and can originate from the external carotid or one of its branches about the ear or from the sigmoid sinus and jugular vein. The only effective treatment is surgery. It usually is necessary to operate with the patient under local anesthesia and occlude the carotid and jugular veins in succession to determine from which source the noise arises.

OOPHORECTOMY AND BREAST CANCER

To the Editor:—*What is the status of oophorectomy as a prophylactic measure in breast cancer? Can you give some criteria for selecting cases for this treatment?*

M.D., New Jersey.

Answer.—Oophorectomy as a prophylactic measure in breast cancer has not been effective in reducing the incidence of recurrence or in increasing the time interval from the original treatment until the disease has recurred. In instances of recurrence of the disease after surgical and radiation treatment, oophorectomy and the use of androgens or estrogens, depending on the age of the patient, has held the disease in check for various periods of time and, in some instances, has caused complete regression. In breast cancer complicating pregnancy, bilateral oophorectomy at the time of cesarean section has produced regression in a number of cases treated in our clinic. It has been recommended as a routine procedure in this situation.

DIATHERMY

To the Editor:—*What, if any, advantage does microwave diathermy have over short wave diathermy? Is there any evidence that microwave diathermy may cause cancer?*

Charles D. Rollins, M.D., Henderson, N. C.

Answer.—Both short wave and microwave diathermy are used therapeutically to heat tissues. Since both are effective heating agents, it is difficult to say that one has any particular advantage over the other. There is no evidence to show that either produces cancer.

DIPLOPIA

To the Editor:—*Is double vision sometimes observed following ankylosis of the temporomaxillary joint? If so, is it directly related to ankylosis?*

E. Trible Gatewood, M.D., Richmond, Va.

Answer.—There is no definite clinical association between diplopia and ankylosis of the temporomandibular joint. The only association between this joint and the ocular muscles is the Marcus Gunn phenomenon in which there is elevation of a ptosed eyelid in association with opening of the mouth or lateral movements of the jaw. In addition, palsy of ocular muscles in association with the jaw winking has been described. The disease is considered to be either nuclear or very close to the nuclei.

PREVENTION OF ERYTHROBLASTOSIS

To the Editor:—*A woman is five months pregnant and on at least one previous occasion she had difficulty because she is Rh-negative and the child was Rh-positive. Tests for blocking type of Rh antibody show a strong positive reaction in a 1:16 dilution and a weak positive reaction in a 1:32 dilution. The patient's husband is Rh-positive but is known to be heterozygous. Is cortisone of any value in such situations? What is the best treatment in this case?*

William L. Gates, M.D., Sherrill, N. Y.

Answer.—The use of cortisone in erythroblastosis has proved disappointing. It has not prevented the sensitization of babies nor has it resulted in a better prognosis for babies already sensitized. The antibody titer is a poor prognostic guide. Preparations should be made prior to the delivery for an immediate exchange transfusion if the newborn has a positive Coombs test and a hemoglobin level of less than 15 gm. per 100 cc. If the serum bilirubin level rises above 20 mg. per 100 cc., the exchange transfusion should be repeated. It may be necessary to carry out this procedure three or four times in the first 48 hours in order to keep the serum bilirubin content at a safe level. Experience has demonstrated that these multiple exchange transfusions primarily reduce the bilirubin level and thus prevent serious damage to the baby by this toxic substance. Multiple exchange transfusions have improved tremendously the prognosis of the baby with erythroblastosis who is born alive.

RHINOLALIA

To the Editor:—*Because of progressive deafness due to middle ear disease an adenotonsillectomy was done on a 5-year-old boy. Preoperatively his voice was normal, but postoperative marked rhinolalia has persisted for four months with no improvement. In infancy a cleft soft palate was successfully repaired. What is the treatment and prognosis?*

M.D., New York.

Answer.—A patient who is born with a cleft palate may have an abnormality involving the pharyngeal opening of the eustachian tube. This does not always occur, but sometimes when it does occur, difficulty in hearing may ensue. Prior to the adenotonsillectomy performed on this 5-year-old patient who had a cleft of the soft palate repaired in infancy, speech was normal. The postoperative rhinolalia may be due to scar contraction of the anterior pillars. One must also consider any injury to the soft palate during the operation. If scar has resulted in the soft palate because of the operation, nasal speech may result. This situation can frequently be corrected by means of massaging the palate and speech therapy by a person trained to handle children with cleft palates. The results should be very satisfactory.

HAZARDOUS DRY CLEANING AGENTS

To the Editor:—*Is any form of toxic peripheral neuritis caused by the chemical reagents commonly used in dry-cleaning establishments?*

Stanley L. Clayton, M.D., Denison, Texas.

Answer.—The chief dry cleaning solvents at this time are chlorinated hydrocarbons such as carbon tetrachloride and trichloroethylene and petroleum derivatives such as naphtha and Stoddard's solvent. On a numerical basis, the major opportunity for exposure in a dry cleaning plant is the spot remover's table. This work is a petty art rather than a science or a trade, as every spot remover cherishes a few secret concoctions so that the range of possible exposure is high. Such harmful substances as hydrofluoric and oxalic acids are likely to be on every spot remover's table. Notwithstanding multiple possible exposures, it is not known that any of these substances provoke peripheral neuritis as the sole and characteristic response. On a remote basis, however, it is possible to associate peripheral neuritis with the chemicals of the dry cleaning trade. Some substances like carbon tetrachloride interfere with vitamin metabolism. In the presence of certain vitamin deficiencies, peripheral neuritis is commonplace.

ACTINIC DERMATITIS

To the Editor:—*A girl, aged 3½, has "actinic" dermatitis. This child has a maternal aunt with proved lupus erythematosus and another maternal aunt with "probable" lupus. The textbooks state that exposure to sunlight in such a patient should be avoided. This is practically impossible in a preschool child. I wonder if any time limit per week should be set and if various lotions that are recommended for protection are worthy of use.*

Robert L. Pavy, M.D., Lafayette, La.

Answer.—Lupus erythematosus is not thought to be a gene dermatosis. Some patients with lupus erythematosus are sensitive to sunlight. The child with actinic dermatitis should be helped by application of the following cream to the exposed areas of skin: 15% *p*-aminosalicylic acid and 15% titanium dioxide in hydrophilic ointment—U.S.P. and by the wearing of a hat, long sleeves, and jeans. In the fall it would be well to expose her skin to gradually increasing amounts of sunlight.

CRIMINAL ABORTION EIGHT YEARS AGO

To the Editor:—*Are there any residual physical signs that would be valid as court evidence to prove that a woman had a criminal abortion 8 to 10 years before? She has had marital sex relations. There has been no pertinent gynecologic disease. The woman has had no children since the abortion.*

M.D., New York.

Answer.—It is extremely doubtful that one could find specific physical evidence of a criminal abortion carried out 8 or 10 years previously. Evidences of trauma to the cervix need not be ascribed specifically to an abortion. Residual evidences of pelvic inflammatory disease and failure to conceive could have their origin in conditions other than an abortion.

SINUSITIS IN CHILDREN

To the Editor:—*In the Sept. 26, 1953, issue of* The Journal *in the answer to a question about the treatment of sinusitis in children, no mention is made of x-ray therapy, which is a valuable adjunct in the treatment of this disease. It should be seriously considered whenever a child fails to respond to the usual conservative treatments. As indicated in my paper in the* Journal of Pediatrics (39:223 [Aug.] 1951), *and as supported by many authorities, x-ray therapy is definitely worth trying before antrostomy or any operation is contemplated.*

TREATMENT FOR CORAL SNAKE BITES

To the Editor:—*In the Queries and Minor Notes on "Treatment for Coral Snake Bites"* (The Journal, *Sept. 12, 1953, page 173) the consultant answered "The rational treatment for coral snake bite would be, of course, the administration of suitable antivenin but the consultant is not certain whether such an antivenin is available." In preparing material for publication I have recently had occasion to read a bulletin that sheds additional light on this subject. The authors of the bulletin "Venomous Snakes of Texas and the First Aid Treatment of their Bites" (Bulletin No. 31, Texas Game and Fish Commission, Austin, Texas) state, "Because coral snakes cause such few bites in the United States no serum to neutralize the venom is manufactured in this country but in South America where these snakes are common and reach a length of five feet a serum against the poison is being produced by the Instituto Butantan at São Paulo, Brazil. This serum is sometimes available at the larger zoos throughout the United States."*

ADVANCES IN TREATMENT OF ACUTE AND CHRONIC RENAL INSUFFICIENCY

A. C. Corcoran, M.D., Cleveland

Renal insufficiency is defined for this discussion as a defect in excretory function that interferes with well-being or even places life in jeopardy. The acute insufficiencies result from more or less selective toxic or ischemic damage to tubule cells, they are usually associated with oliguria or anuria, and their course is toward recovery by cell regeneration; hence, the aim of treatment is to maintain the patient until this predictable repair has been adequately effected. In contrast, in chronic renal insufficiency, blocks and masses of nephrons have usually been destroyed beyond repair. Many patients with chronic renal insufficiency can be maintained in comfortable and useful life in spite of severe defects in renal function, but treatment is essentially palliative and the ultimate prognosis commonly grave.

The causes, lesions, courses, and therapeutic aims are different in acute and chronic renal insufficiency. In both, however, the basic principles of treatment are the same. These are, first, to reduce the load of metabolites that the kidney is called on to excrete and, second, to correct specific defects of body chemistry as they appear.

EXPERIMENTAL STUDIES

Perhaps the most significant single experimental fact is that potassium intoxication is the proximate cause of death after nephrectomy. Toxic effects of protein catabolism have been repeatedly demonstrated in experimental total and subtotal renal insufficiency, and a perverted protein metabolism may occur. I,[1] among others, have shown that high calory nonprotein diets prolong life after nephrectomy, but we have been unable to confirm claims of beneficial effects of testosterone or desoxycorticosterone.

The development of the artificial kidney by Kolff and its elaboration by others has lead to a variety of clinical and experimental studies in vividialysis. A particularly important finding of these studies is the fact that in animals that have had nephrectomy and that have been kept alive by any of these methods, severe hypertension and necrotizing vascular lesions often develop. The lesions seem to result from some poorly understood effect of renal insufficiency and are greatly intensified by hypertension. Some investigators relate the hypertension to excessive retention of sodium and water. Preliminary observations by Kolff on the distribution of sodium 24 in dogs so treated tend to support this. As Muirhead and co-workers [2] point out, however, the mechanism of this condition is still obscure, a lack of information partly attributable to technical difficulties in the precise study of water and electrolyte metabolism. At least, the fact that fluid and electrolyte overloads precipitate vascular lesions in dogs that have recently had nephrectomy [3] has the clinical implication that such overloads should be avoided in patients. The occurrence of vascular lesions in animals maintained by vividialysis has the further implication that there is little promise of indefinite arenal survival in current techniques. Lastly, the vascular lesions precipitated by renin in dogs that have had nephrectomy or in rats that have been treated with adrenal steroid materials may bear on the mechanisms that operate in clinical renal disease, in which the renal pressor system is presumably operative.

CHRONIC RENAL INSUFFICIENCY

The association of the syndrome of uremia with azotemia suggests that it results ultimately from some product or process of protein catabolism, although many symptoms of uremia could result from disturbances in electrolyte and water distribution. No "uremic toxin"—should such exist—has been demonstrated. That it is not urea is apparent from the comparison of results of dialysis of patients against baths containing urea; the clinical uremia improves, while chemical uremia is unchanged.[4]

[4] Merrill, J. P.: The Use of the Artificial Kidney in the Treatment of Uremia, Bull. New York Acad. Med. **28**: 523-531 (Aug.) 1952.

The etiological connotation of the term uremia is inappropriate. We have, however, done better than we knew by retaining it, since it directs attention to the therapeutic need for reducing protein catabolism to a reasonable minimum. This aim is achieved by supplying a diet adequate in calories but limited in protein, by eliminating infection, and by adding to these measures rest and reassurance.

Diet.—Protein restriction is far from new. Its recent more rigid application stems largely from the realization that nitrogen balance can be secured from diets that, like the Kempner rice diet, contain as little as 20 gm. of protein. Particular dietary schemes designed for greater palatability and more appropriate electrolyte distribution than the rice diet have been outlined by Borst[5] and Kolff.[6] Both of these observers use fat-sugar mixtures to decrease bulk while increasing caloric supply. These mixtures are useful but tend to cause nausea and should be prescribed in cautious daily increments beginning at a level of 15 cc. four times a day between meals. The consensus is that the aim is to provide between 2,000 and 3,000 calories and a sufficient restriction of protein (40, 30, or 20 gm. daily) to achieve minimal azotemia.

Infection.—Infection stimulates protein breakdown. It can, therefore, precipitate or aggravate uremia and in the form of pyelonephritis, which is common and frequently overlooked, contributes to further renal damage. It is urgent, therefore, that infections be looked for. In this regard, the antibiotics have enormously facilitated control of chronic renal disease.

Rest and Reassurance.—Both physical activity and anxiety increase metabolic rates and catabolic loads. Rest should be generously prescribed and secured, if need be by liberal use of materials that can be metabolized, such as barbiturates, trichloroacetaldehyde (Chloral), or, terminally, paraldehyde administered orally or rectally. The opiates are to be avoided. The direction of terminal care was described well by the late Thomas Addis.[7] Recently, advantage has been taken of the knowledge that sodium lactate in doses of from about 80 to 160 mEq. of a hypertonic solution sometimes increases renal function by a margin that, small in absolute terms, is claimed to stave off uremic symptoms.[8] Our experience with this regimen is small and to date unrewarding.

Electrolytes.—Correction of specific defects in body chemistry applies principally to electrolytes. Apart from the general principle of symptomatic relief of acidosis with sodium bicarbonate and the associated general measure of alimentary phosphate withdrawal by aluminum hydroxide gels (30 cc. four times a day), the major problems in this area occur in those patients who ha relatively specific and disproportionate damage to fur tions of electrolyte excretion. Such are the "sodiu wasters." These, without their individually determin sodium supplement, drain themselves into a state of hyp natremia and reversible uremia.[9] A related change is t syndrome of renal acidosis in which calcium loss resu in osteomalacia, which is relieved by administration alkali. These patients commonly tend also to waste pot sium, sometimes to the point of distressing hypokalem Hypokalemia may supervene in the absence of bo lesions. One such patient was carefully studied by Earle Another, who I saw in association with Dr. Willi Proudfit, strikingly illustrated the range of functional d sociations in chronic renal disease. She was unable concentrate or acidify urine or to excrete potassium a rate much less than that of glomerular filtration, wh the plasma clearances of mannitol and *p*-aminohippur (PAH) were normal, and the maximal tubular excreto capacity (Tm_{PAH}) was only slightly depressed. Her wea ness and bouts of paresis were associated with a seru potassium concentration of 2 mEq. per liter. These we relieved and a concentration of about 3 mEq. per lit maintained by supplementing the potassium in her di with potassium salts in doses of from 100 to 200 mE daily. The underlying renal disease in this patient, as many with renal acidosis, was apparently chronic py lonephritis. Attention is drawn to this exceptional ca merely to emphasize the unpredictable occurrence disproportionate remediable defects of electrolyte exc tion in some patients and the need for individualizati in prescribing content of electrolytes.

As to water, azotemia creates an osmotic diuresis which the nephrons tend to excrete a urine having t osmotic activity of plasma. This adaptation, as it is term by Platt,[11] obligates water output so that the patient ten naturally to determine his own optimum under the stim lus of thirst. When, for any reason, he is no longer ab to do this, dehydration and intensified uremia result, an fluids, usually glucose in water given parenterally, mu be supplied in amounts that will maintain a urinary outp of about 2 liters daily.

Dialysis.—Vividialysis is infrequently indicated chronic renal failure. The clinical response is common transient and often unimpressive. Exceptions occur patients in whom infection, trauma, or exacerbations renal disease have precipitated recoverable uremia an apparently, in some patients with polycystic renal diseas Merrill[4] observes that "the polyuric normotensive patie responds better (to hemodialysis) . . . than does the rel tively oliguric hypertensive," and he makes note of th distressing illusory hopes that the availability of "artifici kidneys" have raised in the minds of patients and the families. No less disappointing have been press notices kidney grafts. Such operations are properly approache primarily as an exact technical and biological study; thi has been the approach of the group at Peter Bent Brighar Hospital.

Hypertension.—The syndrome of malignant hyper tension may appear as a complication of chronic rena disease and may rapidly accelerate the deterioration o cardiac and renal status. When hypertension seems to b damaging per se, as it is in these patients and in those with cardiac failure, it is now possible to reduce diastolic pressure to reasonable levels, such as 110 mm. Hg, by cautious parenteral use of hexamethonium. This treatment has the risk that undue hypotension or even normotension may precipitate total renal failure. The dangers, difficulties, complications, and essentially palliative nature of such treatment should be explained to the patient or to the family. The treatment should be begun in the hospital. The initial intramuscular dose is determined from the response of arterial pressure to an intravenous test dose given slowly. The spacing and size of subsequent doses are determined by careful, frequent observation of blood pressure, azotemia, urine volume, and side-effects since, in renal failure, the drug is excreted slowly. Such treatment is not generally recommended. It should probably be reserved for those patients whose understanding is such that they can continue self-treatment at home.

ACUTE RENAL INSUFFICIENCY

In the recent past the two major hazards to the anuric patient were fluid overloads and potassium intoxication. These dangers have not been wholly eliminated. Still, one major advance is the now widespread recognition that overinfusion is both futile and dangerous, an area of information to which Strauss,[12] among others, has contributed greatly. The consensus now is that fluid replacement should be limited to estimated losses plus from 0.5 to 1 liter of water. It is, therefore, most important to measure all the excretions.

Potassium intoxication in anuria occurs because the catabolism of 70 gm. of protein, as might occur in one day's total fast, releases 140 mEq. of nonexcretable potassium; therefore, in acute as in chronic renal disease, protein catabolism should be reduced to a minimum by the provision of at least 400 Cal. daily in the form of glucose of invert sugar. Full caloric maintenance at a level of about 2,500 Cal. is recommended by Borst [5] and Kolff.[6] This procedure is not accepted everywhere [13] and it is always difficult. Data that might unequivocally show the advantages of carbohydrate calories in excess of the recommended minimum should be made available. In the interim, the practice is to exceed the minimum whenever practical, as by the use of fat-sugar emulsions in those persons who can accept them.

Many patients require maintenance of caloric intake by intravenous routes. The problem that arises is how to give adequate calories without damaging veins or burdening the patient with fluid. In general, intravenous therapy is best conducted by a constant drip through a polythene venous catheter. It can be assumed that patients who are febrile and who have an infection require more than the minimum of 400 Cal. daily. They are probably advantageously given 40% dextrose solution through a catheter placed in the iliac or caval veins through femoral venipuncture.[14] In post-traumatic renal failure from battle wounds, Capt. Paul Teschan seems to have shown the advantage of this mode of caloric supply.

Carbohydrate rations not only tend to prevent hyperkalemia but, when deposited as glycogen, cause the storage of potassium. Insulin (1 unit to 3 gm. of dextrose) is advantageously added to the dextrose drip if hyperkalemia develops. The toxic myocardial effects of potassium can be temporarily antagonized by adding calcium gluconate in doses of from 10 to 20 gm. per 24 hours. These measures can be effective only over the course of hours or days. If anuria and hyperkalemia persist other modes of potassium elimination must be used. The two made recently available are cationic exchange resins (ammonium-sodium cycle) and vividialysis. Potassium can be removed effectively by intestinal lavage, but the effects of this on fluid and electrolyte distribution are hard to control.

As for the resins, their oral or rectal use demands careful control of sodium uptake and withdrawal. Given orally, they are not well tolerated; rectally, they are less efficient adsorbents but still can withdraw about 0.3 mEq. potassium per gram of resin. In patients with intestinal stasis, there is definite risk of impaction, so that those who need them most tolerate them least. Further advances are to be expected in this field of therapy.

The remaining alternative in those with severe hyperkalemia or serious uremia is vividialysis. It will rapidly remove potassium from the body and also nearly always elicit a dramatic clinical improvement that may be sufficient to permit the resumption of conservative management with food and fluid given orally. Conservative management without dialysis can yield a recovery rate of 80%.[13] Still, from the aspect of the patient's comfort and well-being, peritoneal dialysis by the method of Grollman [15] or hemodialysis are most useful adjuncts to treatment. Further, in those patients made severely ill by the effects of trauma and infection, as in post-traumatic anuria, conservative management is definitely ineffective and dialysis is necessary for survival.

As the kidneys may "open up," the patient's condition may continue to deteriorate for a day or two because of increasing uremia. More commonly, as diuresis increases, deterioration results from uncontrolled losses of potassium and sodium that occasionally continue for long periods.[16] Fortunately, appetite and a feeling of well-being usually begin to return at this time, so that oral maintenance and replacement become practical, although continued close supervision of clinical and chemical status is necessary. Consequently, patients with acute renal insufficiency require skilled supervision and good laboratory aids even in the phase of recovery. In brief, the management of acute renal insufficiency, particularly when it is associated with trauma and sepsis, requires an unusual amount of time, knowledge, and apparatus, all of which are justifiable because condition is essentially one from which recovery is possible.

SUMMARY AND CONCLUSIONS

Basic principles of treatment in acute and chronic renal insufficiency are similar, although the lesions, courses, and prognoses of these conditions are widely different.

Studies in animals indicate that the possibility of arenal survival is small and suggest that excess loads of electrolytes, notably sodium, are undesirable.

Recent advances in treatment of chronic renal disease consist principally in more rigid use of low protein diets of adequate caloric content and the availability of means of controlling infection. The flame photometer has increased the ease with which disproportionate defects in electrolyte excretion can be recognized and corrected. In contrast to its usefulness in acute renal insufficiency, vividialysis is rarely effective in uncomplicated chronic renal disease. Depressor drugs, notably hexamethonium, are occasionally recommended for the control of hypertension and cardiac failure.

Advances in treatment of acute renal failure consist principally in improved conservative management and the availability of means of vividialysis. Conservative treatment consists essentially of fluid restriction, provision of a minimum of 400 carbohydrate calories daily, and control of hyperkalemia with dextrose-insulin-calcium mixtures and, when practical, cationic resins. Those persons who are severely ill require dialysis. Trauma and infection severely impair the efficacy of conservative management. The possibility of substantial recovery from and the complex course of acute renal insufficiency make it a condition that requires skilled supervision and adequate laboratory study.

ADVANCES IN MANAGEMENT OF THE NEPHROTIC STATE

John A. Luetscher Jr., M.D., Quentin B. Deming, M.D., Ben B. Johnson, M.D.
and
Carolyn Forman Piel, M.D., San Francisco

The nephrotic state is a well-defined clinical entity without a generally accepted name. Nephrosis, lipemic or lipoid nephrosis, the nephrotic syndrome, and other names carry with them certain implications of etiology, pathology, or prognosis that are not justified in the present state of our very limited knowledge. For simplicity, the term nephrosis will be used to designate the syndrome of proteinuria, low serum albumin, high blood lipids, and variable edema. Forty-two patients, who have been studied and treated during the past three years, form the basis of the present report. One-half of the patients were 1 to 5 years old at the onset of edema. The age of the other patients varied evenly from 6 to 50 years.

No effort was made to classify patients according to cause (glomerular nephritis or lipoid nephrosis). Although a respiratory infection often preceded the onset of nephrosis, the signs of acute glomerular nephritis were not observed and the evidence of a streptococcal origin was not convincing. Patients who first had very similar signs and urine findings have followed different courses. Some have become entirely well, while a few have had increasing hypertension, hematuria, azotemia, and, at death, lesions resembling those of chronic glomerular nephritis. Did the latter group have a different disease from the onset, or did the glomerular lesions develop at a later stage? The final diagnosis has usually been made in retrospect. Although the late development of sustained hematuria, hypertension, and azotemia has been significant of a bad prognosis, minor and variable hematuria and elevation of arterial pressure and blood urea in the early stages of the disease have been of little prognostic value.

The course, without specific treatment, is one of chronic, fluctuating edema, often modified after an infection. In a few patients, the edema is of brief duration, but it usually goes on for many months, sometimes for years. Infections are frequent, especially in the respiratory tract, the skin, and the peritoneal cavity. In the pre-antibiotic era about one in every three patients used to die of infection. This figure has been greatly reduced. In the present series, there have as yet been no deaths from infection.

The ultimate outcome of reported groups is highly variable. Spontaneous, complete remissions have occurred in as many as 32% of one group of children in whom nephrosis and nephrotic nephritis was diagnosed.[1] In an unselected group of children and adults from another hospital, only 12% of the patients recovered completely, when deaths from infection were eliminated.[2] The remaining patients showed continuing signs of renal disease. Somewhat less than 40% of patients in the published series died with uremia within five years. Better results are recorded in those series from which patients with definite hemorrhagic nephritis are excluded.

The symptomatic improvement that can be achieved with modern treatment has made the collection of a simultaneous control series very difficult. We can describe the immediate changes in the patient's course after certain forms of treatment. The question whether we have modified the ultimate prognosis is still in doubt because of the lack of comparable controls.

AIMS AND MODES OF TREATMENT

Treatment should be directed primarily toward the survival and ultimate recovery of the patient from the renal disease and secondarily toward the relief of edema and other symptomatic manifestations of the nephrotic state. Survival depends on management of intercurrent hazards, notably infection, malnutrition, and massive edema, together with the rarer complications of hyper-

[2] Rennie, J. B.: Oedematous Syndrome of Nephritis with Special Reference to Prognosis, Quart. J. Med. 16:21-31 (Jan.) 1947.

tensive crisis, cardiac failure, and acute exacerbations of renal insufficiency. True recovery is the cessation of activity of the renal lesion. Clinical relief of symptoms and signs may occur with residual evidences of a renal lesion or of its consequences, namely, hypertension. Edema may be worthy of therapeutic attention when it threatens the breathing reserve or makes nutrition a serious problem. Measures directed against edema should be evaluated not only for effectiveness but also for possible risks, both immediate and long-range.

Bed rest stimulates diuresis in only the mildest cases. It is apparently without effect on the outcome of the disease. In addition to its bad effect on morale, prolonged bed rest may cause undesirable shifts of fluid to the genitalia, abdomen, or chest and may predispose the patient to venous thrombosis.

A generous fluid intake is usually prescribed but is not always accepted by the patient. Anorexia may frustrate efforts to improve nutrition. Various special diets have been tried without convincing results. Restriction of sodium intake to less than 1 gm. of sodium chloride per day may be helpful, but this may also impair the total intake of food or may lead to an undesirable reduction of serum sodium concentration. Cation exchange resins have been of very limited assistance and have been poorly tolerated. The conventional diuretics are unreliable. We have not used mercurial diuretics because of the risk of serious immediate reactions and possible aggravation of the renal lesion. Concentrated human serum albumin induces a temporary diuresis in about one-half of the patients who receive 50 gm. intravenously for four or more days.[3] Whole blood may be useful in patients with marked anemia.

ROLE OF INFECTION

The control of preexisting infections and the removal of foci of infection should be undertaken only in accordance with established principles of sound practice, not in the hope of improvement of the nephrotic state.

Intercurrent infection is one of the chief causes of morbidity and death in nephrosis. The upper respiratory tract, the skin, and the peritoneal cavity seem especially vulnerable, and bacteremia is not infrequent. Prompt treatment is essential. The common infection caused by a pneumococcus or hemolytic Streptococcus is controlled with penicillin. Less common and more resistant bacteria of the gram-negative types have appeared with increasing frequency with the widespread use of antibiotics, calling for the use of penicillin plus streptomycin or a broad spectrum antibiotic in immediate treatment. Bacteriological cultures and study of sensitivity of organisms should be made at once in any serious infection.

The long-term administration of antibiotics to avoid recurrent infection has not yet been generally accepted. The replacement of the normal flora with bizarre and resistant organisms presents new problems, and the effectiveness of the prophylaxis is uncertain. We have preferred prompt treatment rather than attempts at prevention.

MODIFICATION OF RENAL LESION

Spontaneous diuresis sometimes follows an infection. Measles and vaccinia have been induced in nonimmune patients, with temporary or lasting benefit. Influenza vaccine has also been followed by improvement in some cases.[4] Nitrogen mustard has been administered with benefit to certain patients, but many undesirable effects are produced.[5] Corticotropin (ACTH), cortisone, and hydrocortisone will be considered in more detail, since their more general use warrants further consideration of their effectiveness and certain hazards.

CORTICOTROPIN, CORTISONE, OR HYDROCORTISONE

Much remains to be learned about the mechanism of action of the adrenal cortical hormones in nephrosis. In addition to the renal lesion in nephrosis with proteinuria, impaired glomerular filtration, oliguria, and sodium retention, there is evidence suggesting some aberrations of adrenal cortical function and of the metabolism of proteins and lipids. Improvement or remission of many of these evidences of the disease may occur either during or after treatment with corticotropin, cortisone, or hydrocortisone.[6]

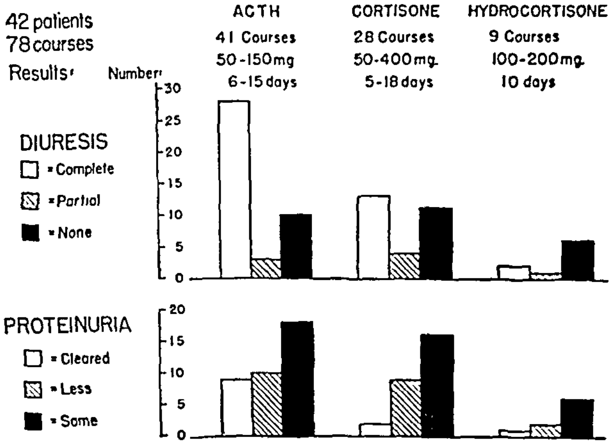

Fig. 1.—Figure shows the immediate effects of the adrenocortical hormones on edema and proteinuria of the nephrotic state. It is evident that the incidence of diuresis and clearing of proteinuria was highest in patients *receiving corticotropin* (ACTH).

In our series of patients, these hormones have been given in full dosage for 10 to 14 days (fig. 1) and then withdrawn abruptly. Shorter periods of administration are less likely to reach a full effect. Treatment for periods

longer than two weeks have generally not been employed for several reasons. There seems to be a diminishing return of benefit with further treatment, if no improvement is evident after two weeks. The hazards of prolonged use of the potent adrenocortical hormones in these patients are considerable. Since we have been reluctant to administer the hormones without hospitalization and the closest observation, the cost in time and expense has been heavy. Furthermore, improvement may occur when the administration of the hormone is stopped. In contrast to prolonged treatment, brief courses are safer and easier for all concerned and offer the double chance for improvement on either treatment or withdrawal.

It is axiomatic that the optimal dosage is one that produces the desired effect with a minimum of undesirable actions. Daily dosage less than 40 mg. of corticotropin or 100 mg. of cortisone is likely to be ineffectual, even in small children. Doses of more than 100 mg. of corticotropin or 300 mg. of cortisone per day are likely to be associated with pronounced side-effects. We suggest as initial dosage in children: corticotropin, 50 mg. intramuscularly per day, divided into four equal doses; corticotropin gel, 20 units twice a day; or cortisone, 200 mg. per day, divided into four equal oral doses or given intramuscularly once a day if oral medication is refused or vomited. Hydrocortisone acetate is effective when given by mouth in dosage comparable to that of cortisone; intramuscular injection of hydrocortisone acetate is apparently less reliable. Older children and adults may be given one and one-half times these doses. If improvement fails to appear, a further course of treatment with larger doses is recommended.

Special Risks in Use of Corticotropin or Cortisone in Nephrosis

- Initial stage
  - Oliguria
  - Increased edema
  - Increased blood pressure
    - Hypertensive encephalopathy
  - Hypotonicity—low serum sodium
  - High serum potassium
  - Increase in azotemia
- Diuresis
  - Potassium depletion
  - Dehydration
  - Peripheral vascular collapse
  - Tachycardia
- Infection
  - Masking of symptoms and signs
  - Rapid spread
  - Failure of antibiotics
- Blood
  - Leukocytosis
  - Thrombosis and embolism

General agreement has not yet been reached on the relative effectiveness of corticotropin as compared with cortisone. We have usually started with a moderate dose of cortisone. If this failed, the next course of treatment was frequently with corticotropin at a somewhat more effective dosage. This approach has been one of convenience, since cortisone can be taken by mouth and the discomfort and slight risk of multiple intramuscular injections in an edematous, infection prone patient avoided. This has weighted the series in favor of corticotropin, since any further treatment may result in improvement after one or more unsuccessful attempts. The data seem to show that corticotropin is slightly more effective than cortisone, but the effects may be due to quantitative differences in the effective levels of adrenal hormones produced rather than to some undetermined qualitative difference in biological action. Repeated courses of treatment favor the opportunities for improvement in resistant cases.

SIDE-EFFECTS OF TREATMENT

The administration of large doses of these potent hormones may lead to the familiar undesirable clinical reactions. In addition to the recognized risks, there are certain unusual hazards in the treatment of patients with nephrosis (see table). When edema and effusions are massive, the further fluid retention, which occurs in the early days of treatment, may produce severe discomfort and further impairment of vital capacity. In such cases, it may be desirable to do an abdominal paracentesis before administering the hormone. Severe restriction of sodium intake is unsatisfactory, since fluid accumulates in any case, while the serum (and extracellular) sodium concentration may fall to dangerously low levels. A diet containing 3 gm. of sodium chloride per day seems to be satisfactory, in most patients.

Small increases in blood pressure are the rule during the use of corticotropin or cortisone. An occasional patient has a sharp rise of pressure, culminating in hypertensive encephalopathy if the hormone is not withheld. The increase in arterial pressure during administration of cortisone appears less than that observed with corticotropin.

Increased levels of urea in the blood are common in nephrosis, and these may rise further with the administration of the adrenocortical hormones. Such changes are usually of no clinical importance, unless the patient is already on the verge of renal insufficiency. The blood creatinine is much more useful in assessing renal functional status before and during treatment because it is only slightly affected by oliguria and increased protein catabolism.

Potassium balance may change in a rapid and unexpected manner during treatment. It is important to check the serum potassium concentration at intervals of two or three days. In the early days of treatment, the serum potassium may rise rapidly to dangerous levels. This can usually be controlled with an increased fluid intake and a reduced potassium content of the diet. As the urine volume increases during later days of treatment, the serum potassium concentration may fall below normal and call for supplements of potassium. Potassium chloride, 3 to 5 gm. per day, will usually suffice, but, during a profuse diuresis, much larger quantities may be necessary to balance the large losses in the urine.

Tachycardia, lowered blood pressure, and dehydration may appear at the end of a rapid diuresis. Extra sodium should be added to the diet, and blood or concentrated human serum albumin may be used to combat hypotension.

Infection has been a frequent and dangerous complication of treatment. Symptoms and signs of infection are often concealed by the antipyretic and anti-inflammatory actions of the adrenal cortical hormones, and a clinical flare-up is frequently observed when administration of the hormones is stopped. The leukocytosis that regularly develops during treatment may be misleading. The benefits of hormonal treatment may be blocked or interrupted by an infection. Routine administration of full therapeutic doses of a broad spectrum antibiotic prevents many of these hazards, but infection with resistant organisms may occur. Any new symptoms or signs should stimulate a careful search for infection. Hormone administration should be withdrawn if rapid spread of infection occurs.

Venous thrombosis and embolism may occur spontaneously in nephrosis. Since these complications may possibly be precipitated by infection and by adrenal cortical therapy, a careful watch should be maintained.

COMMENT

The improvement that follows the use of corticotropin or cortisone in nephrosis varies from complete remission to no measurable effect. Repeated courses of treatment may produce further beneficial effects. If relapse occurs after a period of improvement, another course of treatment is indicated. When remission lasts for more than six months, the outlook is good; relapse after a year's remission is rarer (fig. 2).

A much longer period of observation will be necessary to evaluate the final result, but certain conclusions can be drawn from the available data. Approximately 43% of both the adults and the children who have received corticotropin or cortisone, or both, have now been apparently well for more than one year (fig. 3). This result is encouraging, but it is only slightly better than the spontaneous outcome of some groups of patients who did not receive adrenal cortical hormones. Two additional questions arise. Are the risks of hormonal treatment justified by the results? Can we do better with any other plan of administration of the adrenal cortical hormones? These questions are related, since the larger dosage and more prolonged treatment, which have been suggested, may well increase the incidence of undesirable hormone actions.

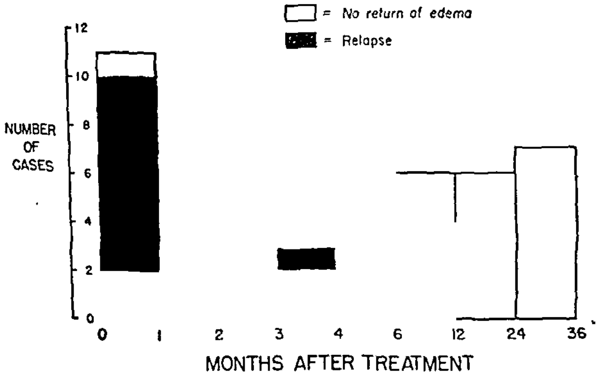

Fig. 2.—Duration of relief of edema after treatment with corticotropin (ACTH), cortisone, or hydrocortisone is shown. Edema reappeared in the first month after treatment in 23% of patients and relapses occurred in 6% during each of the next five months. Edema did not recur after it had been absent for one year.

Severe complications and a few deaths have been reported during the administration of very large doses of corticotropin.[6e] We have preferred to use a more cautious therapeutic approach, since some patients who fail to respond to treatment recover spontaneously. If more patients are to be helped, more prolonged treatment may be helpful.[7] This approach would seem most attractive in those patients who respond to treatment with complete disappearance of signs of the renal lesion, only to relapse after the end of treatment and ultimately to progress to signs of glomerular nephritis and uremia and then to death. Insufficient data are available at this time to evaluate plans for long-term treatment. Therapeutic enthusiasm should not obscure certain inevitable problems of long-term treatment, especially the cumulative hazards to the patient and the heavy burden of constant medical attention necessary for the patient's protection.

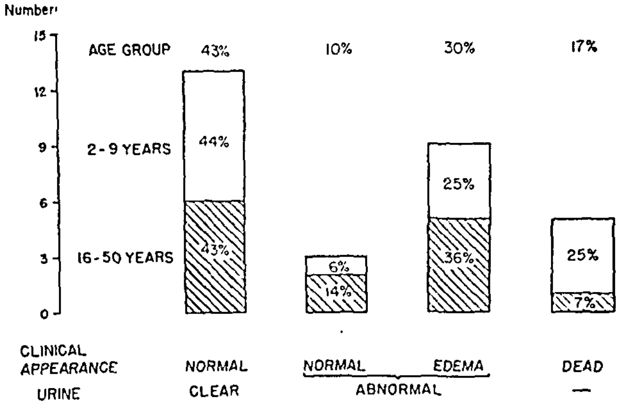

Fig. 3.—Figure shows clinical status and status of urine in patients followed for more than one year after treatment. Percentages at the top of each block are for all ages; open areas represent children and shaded areas adults. About 43% of children and adults recovered from nephrotic state after treatment.

SUMMARY AND CONCLUSIONS

Observations are made on the effects of treatment of 42 children and adults in the nephrotic state. Prompt treatment has been effective in the control of intercurrent infection. Continuous administration of antibiotics for prophylaxis has not been used except during treatment with cortisone or corticotropin (ACTH).

Treatment with cortisone or corticotropin apparently shortened the nephrotic episode in certain patients. The lack of comparable controls makes it difficult to be certain whether the ultimate outcome of the whole group has been improved. One or more courses of treatment with moderate dosage of cortisone or corticotropin for two weeks has reduced or eliminated symptoms and signs of the nephrotic state in a large proportion of the patients. Repeated relapse or failure of treatment calls for some change in the plan of treatment. Larger dosage or more prolonged treatment with cortisone or corticotropin may be indicated in selected cases, but some increase in the hazards of treatment must be anticipated and controlled.

OUTLOOK FOR PATIENTS WITH GLOMERULONEPHRITIS

Norman M. Keith, M.D.
and
Howard M. Odel, M.D., Rochester, Minn.

Bright realized early in his studies that renal disease was a complex problem.[1] He stressed the relationship of renal dysfunction and abnormality to general edema and cardiovascular abnormalities. In addition, he recognized the development of metabolic disturbances as the disease progressed and, for a better understanding of their significance, invited the cooperation of the chemist. The results of this joint venture, though meager, anticipated by 75 years some of the biochemical findings now thoroughly appreciated by the medical profession.

The early students of diffuse nephritis realized the serious outlook for the patient suffering from the progressive form of the disease. They learned slowly, however, that there was an acute reversible type [2] that often healed, and that some of the patients with the chronic form lived and were able to work for a number of years. Bright, after a decade of study,[1b] partially reversed his earlier gloomy predictions with regard to the latter group and stated, "I believe with care its fatal effects may be kept at bay and a hazardous life may be protracted for many years." This was also the viewpoint in succeeding generations of such authorities as Johnson,[3] Bartels [4] and Roberts [5] and others.[6] Bartels and Roberts went a step further and stated that they had observed patients who had chronic parenchymatous nephritis but later recovered.

To clarify our present conceptions with regard to the course of diffuse nephritis, a group of us in Rochester made a follow-up study of a special series of 50 patients who had acute or chronic glomerulonephritis or lipoid nephrosis. We endeavored to make the diagnosis as accurate as possible and thus to avoid cases of a mixed type, which have in the past confused similar studies. Only cases of which we have records for nine and one-half years or more were included; actually some patients we observed over periods of 20 to 40 years (table 1).

The data of this follow-up study were obtained by (subsequent visit and examination, (2) letter from patie or patient's near relative, (3) letter from patient's hor physician, (4) sometimes on change of address, throu a credit bureau, or (5) statement from the municipal state bureau of statistics in case of death in certa instances.

Periodic investigation of the individual patient i cluded a clinical evaluation, appropriate chemical es mations of certain constituents of the blood and uri and specific renal functional studies. These observatio were frequently made during a period of hospital ca and therapeutic investigation. Our chief objective h been the accumulation of significant data during the lon term course of the disease and the interpretation of th value as to the initiation of treatment and as to prognos

RESULTS

1. *Acute Glomerulonephritis.*—Our results in a sm series of eight cases of acute glomerulonephritis w regard to age, sex, and duration of the disease confirm previous investigations.[6b] All our patients were mal aged 11 to 63 years. Five were young adults, but thi were in the sixth and seventh decades. All our patie recovered, the duration of their illnesses varying fr one month to three years. Subsequent to the patien recoveries, we observed them for from 10 to 26 yea In none was there a recurrence of the disease nor c cardiovascular alterations develop in any. In a sin patient, renal disease was accompanied by hyperthyroi ism, which responded satisfactorily to surgical treatme In another patient, aged 11 years, during the first we of illness, renal function, particularly the excretion urea, was seriously reduced, the concentration in t blood rising to 376 mg. per 100 cc. Within two weeks had fallen to a normal level. Some years later this patie was inducted into the armed forces, served his term, a was discharged in excellent health. Our experience wi these eight patients confirms a statement made by Joh son, in 1889 [7] that patients who have acute nephritis m recover in a similar manner to those who have acu bronchitis or pneumonia. Bartels, however, in 187 warned the profession that there may be fatal cases acute nephritis, and acute fulminating cases still occu Statistical studies carried out in recent years, both c children and on adults, indicate that a large percenta of these patients recover. The most satisfactory resul appear to be in patients who receive early and adequa medical care.

2. *Lipoid Nephrosis.*—It is agreed by all that lipoi nephrosis is difficult to distinguish from glomerul nephritis with nephrotic features. Our criterion for di tinguishing the former from the latter was the absence c

diminished glomerular function. We have placed four patients in the group having lipoid nephrosis. Their ages varied from 18 to 24 years. Some data concerning patient H. M. are given in table 2. Three patients were women and one was a man. We have evidence that all four patients recovered. The duration of the disease varied in three from 3 months to 10 years; in the fourth patient we surmise its duration was considerably less than 20 years, although the crucial tests, indicating recovery, were made at the end of that period (table 3). Frequent observations of one of these patients were made over a period of three decades and at no time following recovery were we able to reveal any renal or cardiovascular dysfunction. Murphy and associates [8] and Rennie [9] have reported similar results in some of their adult patients, and Schwarz and associates, Block and colleagues, Barness, Moll, and Janeway,[10] and Riley in certain children.

‡ The duration of the illness was from 3 to 8 years, following which there was no evidence of disease for 19 years. The total observation extended over 28 years.

3. *Chronic Glomerulonephritis.*—The group of patients with chronic glomerulonephritis is of great interest for many reasons. Of the total of 38 patients, 4 recovered, and the life of 34 patients, who had persistent evidence of the disease, was prolonged for from 9½ [11] to 41 years. There have been reports of similar single cases from time to time in the literature. Recovery from chronic glomerulonephritis is indeed a rare event (table 3). One is not greatly surprised that it occurred in a girl and a boy 9 and 16 years of age. Its occurrence in 2 adults, aged 56 and 60, is exceptional, however. One of the latter was also suffering from hyperthyroidism, which responded to surgical treatment (partial thyroidectomy). The other, a 56-year-old man (P. K.), represented really an extraordinary case of nephritis (Bright's disease). During the first year of his illness, hematuria and anasarca were present, and edema was accompanied by a large excretion of protein in the urine, hypoproteinemia, and hypercholesteremia; renal insufficiency was also considerable, the blood creatinine rising to a concentration of 4.2 mg. in 100 cc. and the urea clearance falling to 11 cc.; hypertension and a severe vascular retinitis were present and for a short period pulmonary edema and mental confusion were striking symptoms. He slowly improved during the next 10 months and then returned to work. Renal insufficiency continued for another year. Six years after onset, evidence of renal and vascular disease was lacking (table 4). Six years later the patient died suddenly in a berth of a Pullman sleeping car. Coronary disease appeared to be the most likely cause.

The presence of edema in chronic glomerulonephritis is a difficult and challenging problem. Earlier investigators considered it as primarily renal in origin, but now it is known that general metabolic factors may also play a role. An obvious difficulty in the management of edema is the presence of renal damage. A physician naturally hesitates to stimulate a diseased organ in order to produce diuresis. Nevertheless we believe definite progress has been made in the treatment of the nephrotic syndrome in glomerulonephritis. This advance is due, in great part, to the application of biochemical studies to these patients. In our

TABLE 3.—*Data in Sixteen Cases of Glomerulonephritis with Recovery*

series of 26 cases, the relatively long and favorable course of a decade or more has afforded a unique opportunity for the study of various factors and for appraisal of treatment. In 14 patients, the advent of diuresis led to a loss of 20 lb. (9.1 kg.) or more in weight, the range being 23 to 82 lb. (10.4 to 37.2 kg.). In 12 patients, the loss of weight varied from a few to 18 lb. (8.2 kg.). In patient P. M. (table 5) the loss of 75 lb. (34.0 kg.) during the diuretic period led to some interesting metabolic and therapeutic problems. At the termination of diuresis, the patient weighed 81½ lb. (37.0 kg.), and his appearance reminded one of the starving persons rescued from Germany at the end of World War II. Thus, in this patient, we have striking objective evidence of general wasting of the tissues of the body and from our laboratory study, chemical evidence of disturbances of the metabolism of water, mineral salts, protein, and fat (patient P. M., table 6). Farr and others have previously noted this wasting of the body tissues in the nephrotic syndrome. During the immediate recovery period, patient P. M. ate well and gained in weight without recurrence of edema. On subsequent visits to Rochester during the next 11 months, his weight and appearance were normal with exception of a trace of dependent edema. His renal function continued to be slightly impaired and the serum proteins were still decreased. For the next 13 years, until near the time of his death from uremia, the patient was free from edema and carried on his usual manual work. Surely our experience with this patient suggests further possibilities for the future investigation of metabolic problems in nephritic edema.

* The patient's estimated normal weight was 62.1 kg.

Since the recognition of renal edema by Bright, numerous cases have been reported in which there is a periodicity in its appearance. Addis has reported a series of these cases with recurring episodes of edema and observed that during the edema-free period there may be an absence of proteinuria and hypoproteinemia. We have observed seven such cases in the present series and recorded detailed findings in the urine and blood of patient E. R. (table 7). In this patient, three periods of edema were noted, the first being recorded in his previous history and the second, of a year's duration, in 1938. This was succeeded by a remission of a year and one-half. There then followed the third recurrence of edema, which persisted for four to six years. The edema receded in 1946, and there has been no recurrence up to the present time, a period of seven years. These and similar cases naturally raise many questions with regard to the mechanisms involved. Further study, for example, might give us an insight into the problems of proteinuria and alterations in the proteins and fats of the blood. The periodic occurrence of edema also warns the physician to consider it in the prognosis of the individual patient.

At this point a specific diagnostic problem should be considered. Daugherty and Baggenstoss[12] in 1950 reported a small series of cases characterized by glomerulonephritis, edema, and arthritis. This condition probably belongs to the general group of conditions of which lupus erythematosus is a type. During the nephrotic stage such cases are difficult to distinguish from many of the present series of cases, as we have learned, much to our sorrow. The importance of the recognition of these cases arises from the fact that prognosis up to this date has been very serious, with a rapid course leading to a fatal end.

The later course of chronic glomerulonephritis, after subsidence of edema, has generally been accepted to include a latent period of varying length, which is followed by a period of cardiovascular involvement and progressive uremia. Our case C. A.[11] gives a typical example of such a course. Addis in particular considered this course to be the rule. With more detailed observations during an extended follow-up period, as in this series, we have noted several exceptions. Our attention was drawn to the possible rapid development of diffuse arteriolar disease in 1939. Wagener and one of us (N. M. K.) at that time described the case of a young man, aged 17 years, in which the sequence of events, over a period of five years were as follows: (1) an initial period of six months, during which edema and proteinuria predominated; (2) a period of almost five years of good health, accompanied by proteinuria; and (3) a short terminal period of six weeks, characterized by severe hypertensive disease and renal insufficiency. We interpreted these terminal events as indicative of an acute diffuse arteriolar disease superimposed on a slowly contracting kidney with chronic glomerulonephritis. Necropsy confirmed this clinical conception. Since this experience we have observed the incidence of acute hypertensive episodes in several cases of chronic glomerulonephritis, not only in the terminal phase but at other times during its course. We have seen them subside without specific treatment (for example, patient P. K., table 4). Such experiences emphasize the fact that hypertension may be a reversible process during the course of chronic as well as acute glomerulonephritis.

[12] Daugherty, G. W., and Baggenstoss, A. H.: Syndrome Characterized by Glomerulonephritis and Arthritis: Libman-Sacks Disease with Predominantly Renal Involvement, Arch. Int. Med. 85: 900-923 (June) 1950.

A different type of hypertensive disease developed in one patient (A. K.) of this series. Our records of her case extend over a period of 30 years. When she was 22 years of age, general anasarca, renal insufficiency, and hypertension developed, which after three months responded to hospital treatment; during hospitalization the patient lost 40 lb. (18.1 kg.). In the next seven years the patient appeared to be in normal health except for a persistent trace of protein in the urine. Eleven years later, or 19 years after the subsidence of her initial anasarca, hypertension was discovered for the second time. To all intents and purposes she has continued to have moderate, benign essential hypertension for the last 12 years, with her general health and renal function remaining satisfactory.

In our eight cases of chronic glomerulonephritis in which edema was minor in degree or absent throughout, the latent stage of the disease varied from a few to 20 years. Another patient has been in a latent phase for 22 years; at 53 years of age, she was healthy in every way, except for the presence of a trace of protein in the urine. Five patients passed into the commoner terminal phase of hypertensive disease and uremia.

In two patients essential hypertension developed without distinct renal insufficiency. One of these, patient S. H., later proved to be of exceptional interest and data concerning him were reported in detail by Mulmed, Baggenstoss, and Burchell in 1949. Briefly, his story was as follows. In April, 1926, when he was 9 years of age, acute glomerulonephritis developed. After subsidence of the acute stage, he continued to have a considerable amount of protein in the urine, but hypertension did not develop until 10 years later, in 1936. From that date until his admission to the Mayo Clinic, in May, 1946, hypertension and proteinuria were always present when he was medically examined. At our examination, 20 years after the onset of the disease, the patient was suffering from diffuse arteriolar disease with active retinitis, seen in cases of group 3 (table 8). Bilateral supradiaphragmatic and infradiaphragmatic sympathectomy was performed, and at the time of each operation a satisfactory exploration and biopsy of each kidney were made. The surgeon described them as grossly normal in size and shape. The histological picture of the kidneys was that observed in cases of essential hypertension of the benign type with no evidence of glomerulonephritis. The patient had a favorable immediate response to sympathectomy, with a lowering of blood pressure, especially when he stood upon his feet. During the next five years the patient continued to work, his blood pressure usually measuring systolic 160 to 165, diastolic 120 to 130 mm. Hg. There was no recurrence of the retinitis, and in spite of continued grade 2 proteinuria, his renal function otherwise remained normal.

Our attention was directed in 1944 to a distinctly different and infrequent course of events in chronic glomerulonephritis. In a series of three cases, the patients sought medical advice because of hypertensive cardiovascular disease of several years' duration.[13] Because of the failure of edema to disappear when the first patient was given routine treatment for myocardial failure, urinary and blood chemical studies were instituted, which revealed the presence of lipoid nephrotic features. In this patient the nephrotic syndrome later disappeared. The events recorded in these cases support the conception of Schroeder that some cases in which essential hypertension has developed are primarily cases of chronic glomerulonephritis.

Two important developments have followed the application of renal functional studies to clinical medicine. The first is of diagnostic significance. By aid of these studies, renal insufficiency has been discovered in many more patients and in a greater variety of disease conditions than before their use was instituted. Diagnosis of an obscure uremia, either acute or chronic, has first been made possible by the simple estimation of the concentration of urea or creatinine in the blood. In the second place, renal functional studies are of prognostic value during the course of the nephrotic syndrome, as mentioned previously, and also during other phases of chronic nephritis. Those of us whose work over the years has included the care of patients with chronic uremia recall how often we were surprised at the length of time some of these patients could carry on comfortably.[6a] Such patients reveal a remarkable adaptation of their tissues to very abnormal metabolic conditions.

COMMENT

A review of the natural history of nephritis in this study reveals a variety of courses. The long duration of a satisfactory existence in some of our patients made the follow-up problem much less depressing than anticipated. Acute glomerulonephritis is frequently a self-limiting disease, seldom recurs, and does not seem necessarily to increase the susceptibility of the patient to subsequent chronic cardiovascular lesions. Recovery from the syndrome of chronic lipoid nephrosis takes place in a small but significant number of cases. A rare patient with both the edematous and dry type of chronic glomerulonephritis may recover. Addis' experience with late recovery in acute glomerulonephritis is encouraging. In 1931 he reported data on a few patients who recovered after the disease had persisted for five years; in 1948 he lengthened this possible period to 10 years[6b] (table 9). Our own results and those of others support the viewpoint that lipoid nephrosis and chronic glomerulonephritis may run a protracted course of one to several decades (table 10). The problem of edema is still a stubborn one and has perhaps stimulated as much clinical investigation as any one phase of the disease. Nevertheless the proper use of diets, particularly the control of the intake of sodium chloride and protein, the intelligent use of diuretics and expanders of plasma, the induction of peritoneal and pleural paracenteses, and lately the introduction of cation exchange resins and of corticotropin and cortisone have all proved of therapeutic value. Further study of the antidiuretic substances (the sodium-retaining corticoids of human urine) isolated from the urine of these patients by Luetscher and Deming[14] should offer fruitful results.

* Addis.[6b]

Study of the occurrence of hypertension during the course of glomerulonephritis began with Bright and has continued unabated up to the present time. Bright's suggestion that hypertension might exist in chronic diffuse nephritis arose from his studies of the heart when he examined the morbid appearances in 100 of his cases. The chief structural changes in the hearts in 52 cases consisted chiefly of hypertrophy. After those hearts with disease of the cardiac valves and coats of the aorta we omitted, there remained 22 cases of marked hypertroph generally affecting the left ventricle. This led him to lo for some less local cause for the unusual efforts to whi *the heart had been impelled.* He considered the t readiest solutions to be either that the altered quality the blood affords unwonted stimulus to the heart imme ately or that it so affects the minute and capillary circ lation as to render greater action necessary to force t blood through the distant subdivisions of the vascul system.

It has long been accepted that there is an acute and chronic type of hypertension. The former type is observ often in acute glomerulonephritis, but it is now recogniz as also occurring during the course of chronic glomerul nephritis. It may subside and may recur. A serious fo is frequently associated with the terminal uremic pictu Therapeutic trial of surgical sympathectomy has reveal amelioration in a few patients, as shown by Persike a co-workers[15] and in our patient S. H., reported Mulmed and associates. Benefit has also followed the u of hexamethonium compounds. Since their hypotensi action is due to effects on the sympathetic ganglia, the therapeutic effectiveness again emphasizes the possib role played by the sympathetic nervous system in ren hypertension. A long-continued benign hypertension also observed in chronic glomerulonephritis as in o patients A. K. and S. H. The variations of hypertensi in chronic glomerulonephritis, in regard to time of ons course, and severity, raise speculation as to its etiolo and suggest multiple causative factors.

The present follow-up study emphasizes anew t astuteness of Bright in recognizing the important inte relationships between the occurrence of edema, cardi vascular alterations, certain metabolic phenomena, a renal dysfunction. We think it is of some interest that t significance of these same factors has been pointed out several observers in the glomerulonephritis associate with toxemia of pregnancy. Our experience in this stud has increased our admiration for Bright's basic contributions to the various problems that may arise during the course of glomerulonephritis. Subsequent advances in our knowledge regarding the disease are largely the result of physiological, biochemical, bacteriological and pathological investigations, instituted during the various phases, first described 115 years ago.

SUMMARY

The outlook for the patient who has acute glomerulonephritis is usually good, in regard to both recovery and future health. In contrast, the outlook in lipoid nephrosis and chronic glomerulonephritis is often serious. Our long-term study reveals that a rare patient with either of these diseases recovers, and a considerable number may have a satisfactory course for one or more decades. The application of modern renal function tests has proved of distinct help in their management. The present therapeutic measures available to combat edema appear to be more effective than those employed in the past, and therapy directed to the sympathetic nervous system offers promise of alleviation of hypertension.

CLINICAL APPLICATION OF CURRENT TESTS OF RENAL FUNCTION

William Goldring, M.D., New York

Recent advances in renal physiology and methodology make it possible to assess accurately and quantitatively the discrete excretory functions of the kidney.[1] The functions subject to quantitative measurement are the rate of glomerular filtration, renal blood flow, maximal tubular excretory capacity, and maximal tubular reabsorptive capacity.

The rate of glomerular filtration is measured by means of the clearance of inulin, i. e., the amount excreted per minute divided by the plasma concentration represented by the clearance formula UV/P. Since inulin is filtered at the glomerulus and is neither reabsorbed nor excreted by the tubules, the simple clearance calculation indicates the amount of filtrate formed. The mean normal rate of glomerular filtration is 130 cc. per minute.

The renal blood flow is measured by means of the clearance of *p*-aminohippurate. Since this substance is completely removed from the renal arterial blood during one circulation through the kidneys, its clearance is identical with the rate at which the blood itself is circulated through the kidneys. The mean normal value for renal blood flow is 1,200 cc. per minute.

The maximal tubular excretory capacity represents the actual amount of functioning tubular tissue. When the plasma concentration of *p*-aminohippurate (or iodopyracet [Diodrast]) is raised above the critical level, the tubular excretory mechanism becomes saturated and excretes this substance at a maximal rate. It is designated as Tm, and the mean normal value for *p*-aminohippurate is about 80 mg. per minute.

The maximal tubular reaborptive capacity is an index of the reabsorptive capacity of those tubules supplied with glomerular filtrate. As the plasma glucose level is raised by constant infusion, a point is reached at which the tubular reabsorption of glucose proceeds at a maximal rate; if the plasma glucose is further elevated, glucose filtered in excess of this maximal rate of reabsorption passes into the urine. The mean normal value for the maximal reabsorptive capacity of the tubules as measured by glucose reabsorption is 400 mg. per minute.

These methods have not as yet been sufficiently simplified to make them practicable for routine use. They are, however, of inestimable value when a precise quantitative estimate of individual renal excretory function is desirable. In the practical and routine application of kidney function tests, we are forced by expediency to use qualitative and semiquantitative measurements. This will be so until quantitative measurements of the discrete renal functions are feasible. The tests commonly used now are urea clearance, blood urea, concentrating capacity, dye excretion, and pyelography.

UREA CLEARANCE

Urea is filtered through the glomerulus at the same rate as inulin, but it is reabsorbed by the tubules to a significant extent. The value of the urea clearance, therefore, must be lower than that of the inulin clearance; the difference is quantitatively related to the amount of urea reabsorbed. Data on the absolute urea clearance (fig. 1) show that there is a progressive increase in the urea clearance as the urine flow increases up to 1.5 cc. per minute; the inulin clearance is not influenced by the rate of urine flow. The effect of urine flow is, however, slight when it is between 1.5 and 12 cc. per minute, and the effect of urine flow in this range on the urea clearance may be disregarded in utilizing the clearance of urea as an index of renal function. Urea clearances obtained at urine flows below 1.5 cc. per minute are depressed by factors such as dehydration and lowered filtration rate, which result in values that do not represent the true rate at which the kidneys are capable of clearing urea from the blood and that are, therefore, not acceptable as an index or renal function. When the urine flow is between 1.5 and 12 cc. per minute, the mean value for urea clearance is about 70 cc. per minute per 1.73 square meters.

Since the urea clearance varies closely with the rate of glomerular filtration, both are decreased by the same factors, namely, dynamic and reversible changes in intraglomerular pressure induced by changes in the tone of the afferent and efferent arterioles, organic and irreversible obliteration of the glomerular bed, organic and irreversible changes in the preglomerular arteries and arterioles, and congestive heart failure. The determination of urea clearance should be made when the urine flow is either constant or falling, since, during a period of increasing diuresis, exaggerated and falsely high urea clearance values may be obtained.

The urea clearance, then, is an expression of the combined excretory functions of filtration and reabsorption. In the normal and under conditions of high urine flow,

From the Department of Medicine, New York University College of Medicine, and the Third (N. Y. U.) Medical Division of Bellevue Hospital.

Read in the Symposium on Recent Advances in Nephritis before the Section on Experimental Medicine and Therapeutics at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

[1] Smith, H. W.: The Kidney: Structure and Function in Health and Disease, New York, Oxford University Press, 1951. Bradley, S. E.: The Pathologic Physiology of Uremia in Chronic Bright's Disease, American Lecture Series, Springfield, Ill., Charles C Thomas, Publisher, 1948.

the urea clearance is 65% of the simultaneously determinded inulin clearance indicating that, in its passage down the tubules, 35% of the filtered urea is reabsorbed. In advanced renal insufficiency, this figure may increase to 90% and indicate that, in this circumstance only 10% of the filtered urea is reabsorbed. This fact leads to the conclusion that reduction in urea clearance and consequent increase in blood urea in renal disease are due to a diminished rate of glomerular filtration of urea and not to increase tubular reabsorption. In spite of its complex mechanism of excretion, the clearance of urea in renal disease may be used for clinical purposes as analogous to measurement of the filtration rate.

Since the clearance technique for any substance is largely dependent on accurate timing and complete collection of urine, specimens must be collected by catheterization of the bladder. It is sufficient to collect two 30 minute urine specimens, with a single blood sample at the midpoint.

BLOOD UREA

If nitrogen and water balance are constant, blood urea concentration varies inversely with the urea clearance. With diminution in the urea clearance, there is a proportional increase in the level of the blood urea. In figure 2 is presented evidence that in both hypertensive disease and diffuse glomerulonephritis there is an inverse linear relationship between the blood urea concentration and the urea clearance. It will be noted that, from the very first decrease in the rate of urea clearance, there is an accompanying increase in the level of the blood urea.

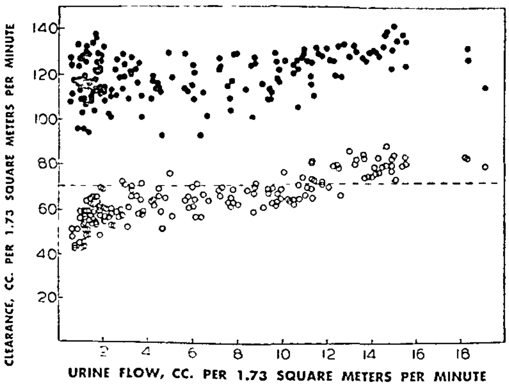

Fig. 1.—186 simultaneous inulin and urea observations in normal persons made during falling or constant urine flows. Dotted horizontal line represents mean plasma urea clearance in normal persons (70.5 cc. per minute); black dots represent inulin clearance; white dots represent urea clearance.

It cannot be accepted that the blood urea concentration rises above "normal" value only after the urea clearance has fallen to 40% of its normal value, suggesting that 60% of the renal parenchyma must be destroyed before there is an abnormal accumulation of urea in the blood. In nitrogen equilibrium, the blood urea rises from the first reduction in the urea clearance. Basis for misconception on this point is found in the following facts. (*a*) The accepted "normal" upper figure for the blood urea is 40 mg. per 100 cc.; actually the average value of a normal subject on ordinary protein diet and water intake is between 15 and 20 mg. per 100 cc. If this fact is ignored, significant minimal increase in the level of the blood urea may be overlooked. (*b*) Variations in nitrogen and water balance may significantly vary the level of the blood urea independently of the rate of urea clearance. It is possible to alter significantly the level of the blood urea by varying the protein intake; the value of the urea clearance remains unchanged (fig. 3). Since patients with renal disease frequently have disturbances in nitrogen and water balance occasioned by anorexia, vomiting, and diarrhea, it may be expected that the level of blood urea will show great variations. These variations may obscure the true relationship between rate of urea clearance and level of blood urea. (*c*) Since the urea clearance is directly related to the rate of glomerular filtration, the same factors that cause variations in the filtration rate vary the rate of the clearance of urea. The blood urea concentration may further increase as a result of decreased urea clearance occasioned by the onset of congestive heart failure in the course of renal disease. Thus, the acceptance of 40 mg. per 100 cc. as the upper limit of normal blood urea concentration and the great variations that occur in its level as a result of disturbances such as nitrogen and water imbalance and congestive heart failure have obscured the true physiological relationship between the blood urea and the urea clearance.

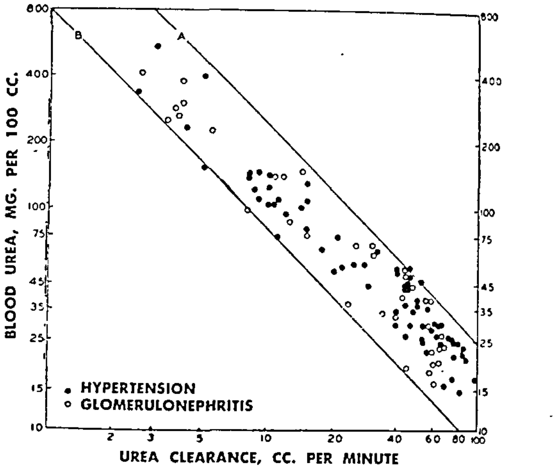

Fig. 2.—Relationship of blood urea concentration to rate of urea clearance in 103 observations in patients with hypertension and glomerulonephritis (urine flows above 1.5 cc. per minute).

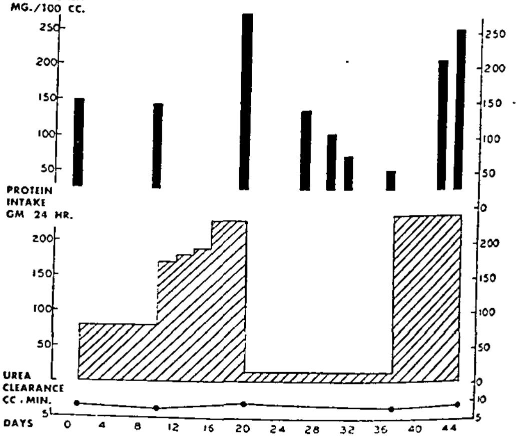

Fig. 3.—Variations in the concentration of blood urea induced by changing the protein intake in a patient with advanced renal insufficiency; urea clearance and 24 hour *urine output remained constant* throughout period of observation.

It is difficult to place certain prognostic significance on the level of the blood urea alone. Since the level of blood urea varies with changes in the rate of glomerular filtration, nitrogen balance, and water balance, all of which may vary independently of the renal disease, it is hazardous to attempt to use the level of the blood urea as an aid in evaluating the extent of renal functional impairment unless its abnormal accumulation is known to be solely the result of functional changes resulting from the intrinsic renal disease. Even if extrarenal factors are reasonably constant, the prognostic significance of the actual level of blood urea concentration depends on whether the intrinsic renal lesion is acute and reversible or chronic and irreversible.

MAXIMAL CONCENTRATING CAPACITY

The measure of maximal concentrating capacity is an index of the kidney's ability to excrete the maximum amount of urinary solids in the smallest amount of water. Normally the kidney is able to excrete urine containing varying amounts of solids as concentrated urine hypertonic to the blood or dilute urine hypotonic to the blood. The total amount of urinary solids can be measured by freezing point depression, surface tension, refractometry, or, for clinical purposes, the specific gravity. The specific gravity of the urine is an additive function of the concentration of its individual solutes. The urinometer measures the specific gravity of the urine and is a simple and adequate method for determining the concentration of the total urinary solids. If a large portion of the renal parenchyma is destroyed by disease, the kidneys lose their ability to vary the amount of solids in the urine, and the maximal concentrating power is decreased; a point is finally reached at which all urine excreted contains a relatively constant amount of total solids. When concentrating power has been lost, the urinary specific gravity is fixed at about 1.010. Normal kidneys can elaborate a urine with a specific gravity of at least 1.024.

Throughout the greater part of the course of hypertensive disease, the water and electrolyte reabsorptive capacity of the tubules is unimpaired, and, consequently, the maximal concentrating capacity of the kidneys is normal. It is not until late in the disease that the maximal specific gravity obtainable falls to values below 1.024; it finally becomes fixed at about 1.010. The reduction in maximal concentrating capacity late in the disease is due to loss of functioning nephrons. The mechanisms accounting for the invariable fixation of specific gravity at the level of about 1.010 are unknown.

Urinary specific gravities of 1.024 or higher may be observed in patients in whom the glomerular filtration rate has been significantly reduced. This dissociation of functions indicates the hazard involved in depending on a single test. When fixation of specific gravity at about 1.010 occurs in the terminal phase, it may persist for months or years and, thus, will not aid in evaluating further renal functional impairment in the course of the renal disease. In this same period, progressive decrease in the rate of glomerular filtration continues to serve as evidence of further functional impairment. In the rapidly accelerated phase of hypertensive disease, the normal concentrating capacity of the kidneys may be maintained to within a few weeks of death from uremia. This same phenomenon of dissociation between normal concentrating capacity and marked decrease in glomerular filtration with elevation of the blood urea concentration is observed in other rapidly progressive renal lesions, such as at the onset of acute diffuse glomerulonephritis. The reverse is frequently encountered for a period of months after clinical recovery from acute diffuse glomerulonephritis when complete loss of concentrating capacity may be associated with normal glomerular filtration rate and normal blood urea concentration.

In addition to its occasional undependability in rapidly progressive renal disease and after recovery from acute nephritis, the maximal concentrating capacity of the kidneys has limited value as a guide to the progressive renal impairment that characterizes the evolution of the hypertensive kidney. The first reason is that this capacity is unimpaired during the greater part of the course of hypertensive disease, despite the fact that loss of renal function can be demonstrated by reduction in the rate of glomerular filtration, effective renal blood flow, and maximal tubular excretory capacity. Secondly, its usefulness is limited by the fact that, when fixation of specific gravity has occurred, the maximal concentrating capacity can give no further information, while quantitative measurements of the discrete excretory functions demonstrate continuing renal functional impairment. These observations reemphasize the importance of multiple tests in evaluation of the multiple excretory functions of the kidneys.

The ability of the kidneys to form dilute urine with specific gravity of 1.001 to 1.004 is directly related to the rate of water excretion. In hypertensive disease, water excretion by the kidneys is unimpaired until late in the disease; the maximal concentrating power is decreased before the dilution is impaired. It is not uncommon for the maximal specific gravity to be reduced to about 1.010 at a time when the kidneys are still able to elaborate a dilute urine with a specific gravity of 1.001 to 1.004. Diluting capacity is finally lost and the specific gravity becomes fixed at 1.010.

It is probable that the loss of diluting power occurring in the terminal stage of hypertensive disease is related to marked decrease in the number of functioning nephrons. The complexity of those extrarenal factors, which affect the rate of the renal excretion of water, is such that the significance of variations in diluting power is difficult to interpret. Also, during recovery from acute diffuse glomerulonephritis, diluting power may return promptly to normal, while complete loss of concentrating power may persist for many subsequent months. The diluting power of the kidneys is, therefore, of little aid in the evaluation of the renal functional status.

PHENOLSULFONPHTHALEIN EXCRETORY CAPACITY

The capacity of the kidneys to excrete phenolsulfonphthalein (phenol red) is measured by determining the rate of excretion in a fixed period of time or the rate of its clearance from the blood. About 94% of injected phenolsulfonphthalein is removed from the blood by tubular excretion. Like iodopyracet and *p*-aminohippurate, although not to the same extent, a large percentage of the phenolsulfonphthalein is removed from the blood in one circulation through the kidneys. This clearance, therefore, can be used to indicate relative variation in the effective renal blood flow. The normal value for phenolsulfonphthalein clearance is about 400 cc. per minute.

Phenolsulfonphthalein excretory capacity of the kidneys in renal disease is affected by specific impairment of the tubules that excrete dye and decrease in effective renal blood flow. The phenolsulfonphthalein clearance exhibits the same trend as the iodopyracet or *p*-aminohippurate clearance. The markedly decreased clearance observed during the terminal stages of renal disease represents the combined effect of decreased renal blood flow and the presence of numerous tubules that have lost their phenolsulfonphthalein excretory power.

The rate of excretion of dye in a fixed period of time is used more commonly as a measure of tubular excretion than is its clearance from the blood. Since the introduction of this test of renal function, the generally accepted method has been the estimation of the dye excreted in the urine in one and two hours after either intravenous or intramuscular injection. Determination of the percentage of phenolsulfonphthalein excreted in a fixed period of time is not as helpful as the estimation of its clearance from the blood because, by the accepted technique of measuring one and two hour urinary excretion, normal results may be obtained even when renal functional impairment exists. The probable explanation for this lack of sensitivity is related to the method used for the collection of phenolsulfonphthalein excreted in one and two hour periods. The intravenous or intramuscular administration of 6 mg. of dye does not raise or maintain plasma levels high enough to reach maximal tubular excretory capacity and, therefore, will not indicate early impairment of function. Actually, the administration of this amount of dye results in plasma levels at which a larger percentage of the dye is removed by the normal kidney in the first 15 to 20 minutes. When one and two hour collection periods are used, the kidneys, despite reduction in the renal blood flow or in their capacity to excrete the dye, are given the opportunity repeatedly to clear the blood of phenolsulfonphthalein. For this reason, a normal value for total two hour excretion may be obtained despite renal functional impairment, but it would differ from the normal in that the rate of excretion in the second hour would quantitatively approach the amount excreted in the first hour, whereas normal kidneys excrete the larger quantity in the first hour.

Remarks

We have used the fractional method of dye excretion by utilizing three 20 minute urine collection periods. The urine is collected by urethral catheterization to insure complete emptying of the bladder, for in a 20 minute collection period incomplete bladder emptying can introduce a source of error. The average rate of excretion in 25 normal persons was 30% in the first 20 minutes and 55% in the first hour.[2]

When phenolsulfonphthalein is used to measure renal tubular excretion, the method of choice is the dye clearance. For routine clinical use, however, the excretion rate in a fixed period of time is adequate, and the fractional technique is preferable to hourly urine collection periods.

INFLUENCE OF SPONTANEOUS VARIATIONS IN URINE FLOW ON INTERPRETATION OF UNILATERAL RENAL FUNCTION

It has been observed that the rate of reabsorption of water by the tubules can vary at the same moment in the separate kidneys in normal persons and in patients with renal disease despite the fact that the kidneys have equal functional capacities. It is possible, therefore, to have different rates of urine flow at the same moment, and, as a result, the concentration of total solids or of specific substance can vary in the urines obtained simultaneously from the two equally efficient kidneys. Inequality in the urine flow from the two kidneys may lead to misinterpretation of comparative excretory tests of renal function. The concentration of urea, phenolsulfonphthalein, or indigo carmine may differ in the urine sample obtained simultaneously from two kidneys with equal function; variations are related to differences in urine flow rather than to unilateral functional impairment.

Differences in urine flow from the two kidneys can also account for significant variations in the appearance time of intravenously administered dye (phenolsulfonphthalein or indigo carmine). There is a large dead space in the collecting tubules, pelves and ureters, and, if the rate of urine flow is significantly lower in one kidney, the time necessary for urine-containing dye to traverse this dead space will be comparatively longer; the appearance time of the dye will vary inversely with the rate of urine flow.

PYELOGRAPHY

The ability of the kidneys to excrete water at different rates has particular significance when related to the interpretation of intravenous pyelography. Differences in the urinary concention of iodopyracet or any substance

2. Goldring, W., and Chasis, H.: Hypertension and Hypertensive Disease, New York, the Commonwealth Fund, 1944.

used as a contrast medium may be referable solely to differences in the urine flow. This difference in concentration of the contrast medium will result in differences in intensities of roentgenologic shadows. Significant variations have been noted in the relative densities of pyelographic shadows in patients studied with kidneys of equal functional capacities. In these instances, a false conclusion might be drawn that the kidney excreting the more dilute urine and consequently producing the more poorly defined shadow was functionally inferior to the contralateral kidney, when, as a matter of fact, renal functional impairment when measured by the precise quantitative tests described was demonstrated to have progressed to the same extent in both kidneys.[2]

The rate of reabsorption of water by the tubules and hence the rate of urine flow may vary markedly in two kidneys of equal functional capacity. Excretory tests comparing the functions of the two kidneys should, therefore, be evaluated with caution for inequality in urine flow of itself can account for variations in urinary specific gravity, urea concentration, appearance time and relative concentration of dyes, and in the roentgen shadow in excretory pyelography.

COMPOSITE KIDNEY FUNCTION TEST

An ideal assessment of the various excretory functions of the kidneys can best be obtained from a composite test (see table). This complete assessment is especially valuable since, under some circumstances, the discrete functions of the kidneys may vary independently of each other. The composite test includes urinary specific gravity after a period of dehydration to measure reabsorptive capacity of the tubules, inulin clearance to indicate the rate of glomerular filtration, *p*-aminohippurate clearance to measure of effective renal blood flow, maximal rate of *p*-aminohippurate excretion to measure maximal tubular excretory capacity, the blood urea concentration, and chemical and microscopic examination of the urine. Preparation of the patient for this test as well as methodology have been described in detail elsewhere.[2]

In cases in which it is not feasible to apply the relatively difficult techniques suggested, comparable information may be obtained by omitting the measurement of maximal tubular excretory capacity and by substituting the urea clearance (or endogenous creatinine) for the inulin clearance and by substituting the fractional phenolsulfonphthalein excretion for the measurement of the effective renal blood flow.

SUMMARY AND CONCLUSIONS

The value and limitations of various kidney function tests are discussed. The ideal measurements involve quantitative estimates of the rate of glomerular filtration, effective renal blood flow, and maximal tubular excretory capacity. For this purpose a composite test is suggested. This composite test may be simplified for clinical use if the more involved techniques are not feasible. This simplification utilizes the maximal urinary specific gravity after a period of dehydration as a measure of tubular reabsorptive capacity, the urea clearance (or endogenous creatinine clearance) and blood urea concentration as an approximation of the rate of glomerular filtration, and the fractional excretion of phenolsulfonphthalein as a measure of tubular excretory capacity.

In view of the multiplicity of renal excretory functions and the fact that in renal disease these may vary independently in each kidney, it is evident that no single test is adequate for complete assessment of the over-all functional capacity of the kidneys.

SURGICAL MANAGEMENT OF ULCERATIVE COLITIS

H. E. Bacon, M.D.
and
H. D. Trimpi, M.D., Philadelphia

Noteworthy progress in the therapeutic approach to chronic ulcerative colitis is rapidly being achieved in the field of surgery. The general practitioner, internist, gastroenterologist, and psychiatrist alike are viewing surgical intervention with increasing assurance, and less and less frequently are seriously ill patients reaching the operating table too late for curative treatment. This fact is self-evident when one examines the remarkable fall in surgical mortalities in ulcerative colitis during the past decade as compared with previous decades. A no less significant observation is the fall in the incidence of emergency ileostomies. By virtue of awakened interest and cooperation between all fields of therapy, surgical measures are well planned and it is common to see the successful completion of total colectomy with cure of the disease brought about in two operative stages or less.

In our series of 331 patients with chronic ulcerative colitis, 81, or 24.5%, have undergone surgical intervention. The post operative mortality is 5, or 3.4%, in 137 operations performed. Four of the mortalities were the result of emergency ileostomies undertaken in almost moribund patients prior to 1946. Of particular interest is the fact that in the last five years it has been necessary to perform emergency loop ileostomies in only two patients. The remaining patients of our surgical group in this period have reached us in time for intensive whole blood transfusions, and antibiotic and electrolyte administration prior to operation. Preoperative preparation has been managed with the cooperation of an internist in all cases and often with the supplemental opinions of a gastroenterologist and a psychiatrist. With this coordinated plan of action it has been possible to perform ileostomy and colectomy in one stage in a majority of

Read before the Section on Gastroenterology and Proctology at the 102nd Annual Meeting of the American Medical Association, New York, June 2, 1953.

patients. There have been no postoperative mortalities in this group, and convalescence has been significantly shortened.

SURGICAL INTERVENTION IN CHRONIC ULCERATIVE COLITIS

All of us are aware of the lifesaving role surgery plays in the patient with intractable ulcerative colitis who is acutely ill and in a toxic state. The indication for surgery in these persons is at once apparent when other remedies fail. It is not this phase of the disease, however, that we are concerned with here, it is rather the so-called borderline patient who experiences remissions and exacerbations and, while at times is very ill, at other times seems to be able to carry on with his occupation. This is the commoner form of chronic ulcerative colitis, and in such persons we do not find the classical indications for operation such as perforation (or impending perforation), hemorrhage, obstruction, abscesses, fistulas, progressive toxemia, and severe nutritional and electrolyte deficiencies. In this chronically ill patient we must carefully balance the advantages to be gained by surgery against the risk of operation and the almost certain institution of a permanent ileostomy.

The greatest single benefit to be achieved by colectomy is the cure of the disease. To the patient this means freedom from episodes of incapacitating diarrhea or dysentery, the termination of arthritic symptoms, a cure of chronic annoying anorectal disorders such as recurring fissures, fistulas, stenosis, proctitis, and others, a curbing of thromboembolic phenomena, a cessation in progressive degenerative liver and kidney changes, and the prevention of primary cancer in the rectum and colon by the removal of a precancerous bowel.

CARCINOMA FOLLOWING CHRONIC ULCERATIVE COLITIS

Despite a preponderance of evidence to the contrary, there are still wishful thinkers who would attribute the incidence of carcinoma in chronic ulcerative colitis to other conditions. Otani and Snapper[1] would lead us to believe that (1) multiple familial polyposis accompanying ulcerative colitis is an underlying etiological factor, (2) adenomatous polyps coexistent with chronic ulcerative colitis undergo malignant changes, or (3) ulcerative colitis is secondary to a stenosing malignant lesion. Our own experience has not supported these assumptions. Each of the possibilities named present distinct characteristics not to be confused with carcinoma arising from chronic ulcerative colitis. In our series of 45 colectomies there were five patients who had large bowel carcinomas, an incidence of 11.1%. In four patients the lesions were unsuspected preoperatively. In no patient were there coexistent adenomatous polyps, familial histories of cancer of polyposis, or diagnoses of chronic ulcerative colitis that did not antedate the discovery of cancer by consid able lapses of time. In only one patient was the hist of ulcerative colitis less than five years in duration. three patients the disease had been present over a per of 15 years or more. In each extirpated colon and rect the carcinomatous lesions resembled one another were not characteristic of the usual carcinomas seen a ing from adenomatous polyps. Invasion of the s mucosa and muscularis was extensive, and the lesi were of a highly undifferentiated type. In two patie metastasis was widespread. For comparison, a pati with familial polyposis (not included in this series) ulcerative colitis of two years' duration was selected. this patient's excised colon, ulceration was widespre with destruction of mucous membrane, but the ade matous polyps were distinct, easily identified, and hi logically differentiated from inflammatory polyps. Th carcinomas were present, and numerous polyps presen atypical changes.

Counsell and Dukes[2] found an incidence of 11. carcinoma in a series of 63 patients undergoing surg for ulcerative colitis. They conclude that chronic ulce tive colitis predisposes to carcinoma, and they feel the extent of this predisposition has been underestima because of inadequate follow-up of patients with ulce tive colitis and because of clinical difficulties in diagno They point out that carcinoma following chronic ulce tive colitis usually grows rapidly and metastasizes ea "It may cause no recognizable surface tumor or ulcer only a diffuse stricture resulting from intramural spr of cancer." Shands, Dockerty, and Bargen[3] describe striking evidence of multicentricity in 19 of 40 patie with adenocarcinoma occurring in chronic ulcera colitis. This suggests that the origin of these second adenocarcinomas is in scattered foci within the muco

When cancer occurs in patients with chronic ulcera colitis, it characteristically develops in late adolesce or early adulthood, and exacerbations are experien intermittently for periods of 10 years or more. Four our five patients fit into this category. In each, can resulted before the age of 50 years. Kiefer and his as ciates[4] write, "A person who acquires ulcerative col in the second decade of life and continues to suffer fr active disease until he is 30 faces a real hazard in possi malignant degeneration." Lyons and Garlock,[5] in th series of surgical patients having the disease for over years, report a 36% incidence of carcinoma. Of 16 tients with ulcerative colitis involving the rectum for o 12 years, in 7, or 43%, carcinoma developed.

Pseudopolyposis is not an uncommon occurrence advanced ulcerative colitis. In our practice we consid it an indication for colectomy. Our reasoning is based the finding of literally hundreds of inflammatory poly in each of the colons of the five patients in our surgic group who were discovered to have rectal or colon cancers complicating their disease. Shands, Docker and Bargen[3] report 19 cases of pseudopolyposis in series of 40 specimens of ulcerated large bowel where carcinomatous change had taken place. In their serie however, histopathological evidence of multicentricity the adenocarcinomas was present in 21 specimens, a of these, 16, or 76.2%. were accompanied by pseud polyposis. The development of inflammatory polyps is a late manifestation that usually takes place after the disorder has been present for six years [6] or more. It is typically found in the healing bowel that is undergoing remission,[7] and this process of healing and remission, with later exacerbation and repetition of the cycle, is the usual history of events in those patients in whom cancer develops. Inflammatory polyps may disappear in many of these patients with long periods of remission,[8] and without doubt it is in these persons that considerable danger exists, especially when the disease has been present for 10 years or more.

It would then seem imperative that patients who have had recurring exacerbations of chronic ulcerative colitis over a long period of time be considered fit subjects for colectomy and excision of the rectum. Indeed, in such persons, even if the hazard of malignant degeneration is not considered, surgical management is mandatory if a cure of the disease and escape from crippling secondary organic changes is to be insured.

CHOICE OF PROCEDURE

In our approach to the selection of an operation for ulcerative colitis we believe that ileostomy alone, as a definitive or curative measure, has no place in the surgeon's armamentarium. Further, we do not recommend ileostomy for any patient unless there is indication that the ileostomy should be accompanied by colectomy or that colectomy should be performed at a later stage. We find one-stage ileostomy combined with colectomy a most acceptable and useful technique.[9] Patients with acute exacerbations or progressive fulminating disease respond dramatically. In contrast to ileostomy alone, we observe that postoperative disability is especially lessened by a more rapid adjustment of the ileum to the functions of the colon in the absence of the colon. There is less toxicity, as evidenced by lowered temperatures and pulse rates. Nutrition, fluid, and electrolyte balance are more quickly restored, and the patient is not faced with greater surgery to follow.

We do not attempt preservation of the rectum with the thought of utilizing it in the future. Despite interruption of the fecal stream by ileostomy, there is a danger of carcinomatous change. Furthermore, it has been evident that, even with the lapse of several years, complete rectal healing is unlikely. Drainage is generally continuous, and there is practically no hope that a once diseased rectum can ever be restored to satisfactory function. Transplantation of the ileum to the anus in an attempt to reconstruct the continuity of the bowel has not been generally accepted. Postoperative complications and difficulties in rehabilitation are greatly increased, and we have not felt justified in subjecting patients to this further surgery.

We have long ceased to feel apologetic or reluctant in recommending permanent ileostomy. The patient and his family are clearly advised, without reservation, concerning the nature of an ileostomy and the care that it will require. That this approach is justified is aptly shown by the average patient, who unhesitatingly learns to care for himself and quickly progresses to complete rehabilitation. Most of these patients are able to assume responsibilities that were unthinkable in their previous physical state.

ACHIEVEMENTS IN SURGERY OF CHRONIC ULCERATIVE COLITIS

Ileostomy.—In the past, most of the complications following operative intervention for chronic ulcerative colitis centered about the ileostomy. Little was known of the nature of electrolyte, nutritional, and fluid losses from this artificial opening. Replacements were often inadequate, with the result that patients were greatly retarded in their convalescence. Today this difficulty has been largely overcome. We are now much more conscious of the importance of fluid, potassium, and sodium deficits. Accurate techniques are available for measuring the circulating blood volume, and we are no longer at a complete loss in estimating nitrogen deficiency. We have newer and better means of supplying calories and proteins, and we are more than ever aware of the great part that whole blood restoration plays in the postoperative course. Newer electrolyte solutions are available for intravenous use. Fewer difficulties related to electrolyte, fluid, and nutritional losses have been noted in the newer simultaneous ileostomy and colectomy procedure because of an earlier adaptation of the ileum to the absorption of these materials.

In the past, ileostomy was often the source of partial or complete intestinal obstruction. This complication could, in almost every case, be traced to haphazard and faulty technique arising from haste and inattention to the fine details of ileostomy construction. Preventable partial obstruction of the stoma due to narrowing of the stab wound or skin incision was overlooked, and usually little or no attention was given to utilizing the cut edge of the free mesentery to anchor the distal ileum. By suturing of this free border to the anterior abdominal wall, torsion or the wrapping of intestine around the illeum was found to be prevented, and prolapse of the stomas was no longer a possibility. The combination of ileostomy with colectomy [10] brought with it the discovery that postoperative adhesions could be considerably lessened by the removal of the diseased colon.

Intermittent or partial obstruction of the ileostomy noted in some of our early patients was often complicated by the development of ulcerative changes in the ileum. Two of these patients required resections of several feet of the terminal small intestine. These experiences with ulcerative ileal recurrences caused by partial obstruction parallel those of McKittrick and Miller [11] and Dennis and Karlson.[12] The care of the skin is of minor concern because of the arrival on the market of simple skintight, lightweight appliances. Attention must be directed to-

ward the placing of the ileostomy to allow for fitting of a correct bag, but if this has been done correctly there need be no leakage of intestinal contents. The Koenig-Rutzen, Jonas, Pierce, and Perry appliances have all been very satisfactory in our hands.

Colectomy.—There is very little doubt today in the mind of any surgeon dealing with chronic ulcerative colitis that a one-stage colectomy is superior to the frequent stages that characterized the operation in the past. A signal advance was attained when the three stage operation, ileostomy followed by colectomy, followed by excision of the rectum, with suitable time intervals between each, replaced the older five-stage or six-stage procedure. In the last few years we have found further progress in the employment of two stages, the first for ileostomy and colectomy, and the second for extirpation of the rectum. Recently we have satisfactorily performed the one stage operation (ileostomy and total colectomy with perineal proctectomy) in seven patients without mortality or increased morbidity.

The technical difficulties of colectomy are few. Considerable judgment is necessary, however, in determining at what point to divide the terminal ileum. If too much small bowel is sacrificed, there are increased postoperative losses of fluids and electrolytes. If too little is removed, the hazard of leaving diseased terminal ileum in situ is a reality. Frozen section has been suggested as being superior to gross study of the bowel to determine the extent of inflammatory involvement, and we would recommend every aid available in making this decision.

A problem arises regarding the site of amputation of the distal large bowel. Experience has taught us to avoid attempts to close any segments of ulcerated intestine leaving them within the abdomen or in retroperitoneal positions. Therefore, we elect to divide the low sigmoid and let the distal segment remain in the lower pole of the wound rather than to amputate the diseased rectum and close the distal segment. Abscess and sepsis are likely to occur. After the occurrence of perirectal infection in two of our patients, we concur with Miller, Gardner, and Ripstein [13] that the conservative measure is best adhered to. An alternative is, of course, to extirpate the rectum at the same time.

Abdominoperineal Excision of the Rectum.—We have had little or no problem in the abdominal approach to mobilizing the distal sigmoidal and rectal segment and removing it via the perineum by means of a modified Miles procedure some weeks after colectomy. In the male, care must be taken not to injure the vas or seminal vesicles, and in both sexes the levators and other perirectal structures are disturbed as little as possible so that bladder and sexual dysfunctions are avoided.

A question arises concerning the advisability of leaving the rectum for future anastomosis. Our experience with this maneuver has been discouraging, and a review of the literature would seem to support our findings. The outstanding complication is a recurrence of the disease in a supposedly healed rectum, even though a year or more is allowed to elapse before the ileum is brought down to anastomose. We performed the procedure in three patients. In two, it was later necessary to reestablish the ileostomy and excise the rectum. In all three cases the rectal manifestations of colitis were mild, and complete healing occurred before anastomosis. Danger of carcinomatous change in the preserved rectum cannot be overlooked because it is well known that cancer will develop even in the absence of the fecal stream, and in ulcerative colitis the rectum is the commonest site for its development.

SURGICAL RESULTS

Of 331 patients with chronic ulcerative colitis who were studied and treated by us, 81, or 24.5%, were operated on. Ileostomy alone was performed in 36 patients, with a mortality of 4, or 11.1%. Colectomy and abdominoperineal excision of the rectum were performed in 45 patients without a single postoperative fatality. Among the 81 patients undergoing surgical treatment a total of 145 operations were performed. Ileosigmoidostomy with colectomy was achieved in three patients, but in two of these it was later necessary to establish permanent ileostomies and excise the rectum. Twenty-eight miscellaneous operations were carried out, consisting primarily of ileostomy revisions. Four patients underwent lysis of adhesions, two had drainage of abdominal abscesses, and in two it was necessary to resect the distal ileum. One of these latter patients died postoperatively. Wound disruption was noted in one patient, but repair was followed by complete recovery. Five patients had carcinoma, and two of these died of carcinomatosis within two years after operation. In the remaining three, who are alive and well, sufficient time has not elapsed to record proper survival evaluations. Of 45 total colectomies and 42 excisions of the rectum, complete rehabilitation has been attained in 41 cases, a rehabilitation rate of 91.1%. Two rehabilitated housewives of the colectomy group became pregnant and successfully carried to term viable infants. In both instances labor and delivery were normal.

SUMMARY

Great achievements have highlighted the progress of surgical management in chronic ulcerative colitis during the past decade. The cooperation of all fields of therapy has been outstanding in bringing the patient who is intractably ill to surgery before irreversible and fatal secondary functional and organic changes have supervened. Of a series of 331 patients with chronic ulcerative colitis treated by us since 1940, 81, or 24.5%, underwent surgical intervention. A total of 145 operations were performed, with a surgical mortality of 5, or 3.4%. Four of these deaths occurred prior to 1946, as the result of emergency ileostomies in practically moribund patients.

Particular attention is directed to the patient with a longstanding chronic illness who experiences exacerbations and remissions every few months or years, and who is never ill enough at any one time to indicate immediate surgical intervention, but who eventually is either totally disabled or succumbs to secondary organic complications. Colectomy must be considered. Weighed against the low surgical risk and the inconvenience of a permanent ileostomy are the benefits of cure of the disease, removal of a precancerous bowel, and prevention of thromboembolic disease and a reversal of degenerative liver, kidney, and arthritic changes.

[13] Miller, G. G.; Gardner, C. M., and Ripstein, C. B.: Primary Resection of the Colon in Ulcerative Colitis, Canad. M. A. J. 60: 584, 1949.

Five cases of cancer complicating chronic ulcerative colitis are reported. These adenocarcinomas were discovered in specimens of colon and rectum from a series of 45 colectomies in which complete colectomy was performed (incidence of 11.1%). In four cases, cancer was not suspected preoperatively. In each specimen the lesions were diffuse, invasive, and of high grade, and there were numerous accompanying inflammatory polyps. We recommend for the surgical management of ulcerative colitis, a two-stage operation, the first stage to consist of ileostomy and colectomy down to the low sigmoid colon and the second stage to be an abdominoperineal excision of the rectum and distal sigmoid. Ileostomy carefully performed concomitantly with the extirpation of the diseased colon affords the patient less difficulty in adjustment than ileostomy alone. Modern appliances and receptacles are lightweight and are easily worn without discomfort or annoyance. The patient is permitted to return to full employment, often to occupations prohibited to him prior to operation because of ill health. Ileostomy, unless it be followed or accompanied by colectomy, is not recommended. Excision of the rectum and distal sigmoid colon must be performed in each patient undergoing colectomy. Of 45 patients undergoing colectomy with excision of the rectum, 41 have been completely rehabilitated (a rehabilitation rate of 91.1%). In the rehabilitation group are two mothers who have recently become pregnant and successfully carried to term viable infants with normal labors and deliveries.

RATIONAL USE OF ANTIBIOTICS IN CONTROL OF SURGICAL INFECTIONS

Frank L. Meleney, M.D.
and
Balbina A. Johnson, B.A., New York

It is a truism to say that the antibiotics have altered the natural course of pathological conditions that have been designated surgical infections. These infections are pathological processes produced in the human or animal body by the entrance of bacteria into the tissues causing either an exudation of leukocytes into a localized area of necrosis or an exudation of leukocytes into a body cavity without necrosis but with the formation of a fibrinous clot. Such pathological processes formerly required a surgical procedure for their control, either excision of part or all of the area of inflammation or incision for removal of the exudate, necrotic tissue, and bacteria that they contain.

The antibiotics have been distributed widely throughout the world, and in places in which they are generally available it is now the responsibility of the surgeon to use them to the best of his knowledge and ability, to prevent bacteria from gaining a foothold in the body when they have entered through the operative wound or at the time of an accidental wound or burn, and to stop their activity as abruptly as possible, if he finds that the bacteria have already become established in the tissues when the patient comes for help. To aid him in those purposes, the surgeon now has available not only his scalpel but eight or nine antibiotics and several other chemotherapeutic agents. Inasmuch as a surgical procedure of itself will often bring the progress of a surgical infection to a standstill, it is at times difficult to be sure that the use of the antibacterial agents in addition or as an adjunct to surgery will achieve these purposes any better than surgery alone. Some time ago one of us (F. L. M.) suggested five criteria by which one could judge that the antibiotics are of some use in surgical infections. These criteria are met when (*a*) the antibiotics obviate the necessity for surgery entirely, (*b*) they permit a less extensive surgical procedure, (*c*) they actually shorten the healing and recovery time, (*d*) they permit a successful primary closure after removal of the focus of infection, which otherwise would not be possible, and (*e*) they permit an earlier secondary closure than would otherwise be done. Further confirmation of the effectiveness of the antibiotics is demonstrated when the purulent exudate suddenly ceases or the wound cultures become negative.[1]

The knowledge of how best to use the antibiotics and which ones to use in any given case is imperative. If penicillin were a panacea or the only antibiotic available, the decision would be easy, but the very multiplicity of antibacterial agents, each with its respective advantages and disadvantages, makes the wise choice difficult. Undoubtedly more antibiotics will be discovered and will complicate the picture still further. It is our hope that this paper will transmit some of our experience in this field.

It requires continuous vigilance, but the rewards are gratifying when infections respond to specific therapy. This vigilance is essential because every accident and every surgical procedure has the potentialities of infection and at least one-third of the cases on a general surgical service are problems of infections well established before admission to the hospital.

It is our purpose to outline a program of procedure so that more patients will have the fullest benefit of our knowledge of the antibiotics. It is also our aim to restore the patient as soon as possible to normal form and function and thus shorten disability, minimize economic exhaustion, and prevent physical disfigurement or death.

Read before the Section on Surgery, General and Abdominal, at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

From the Department of Surgery, Laboratory for Bacteriological Research, College of Physicians and Surgeons, Columbia University, and the Surgical Service of the Presbyterian Hospital, New York.

[1] Meleney, F. L.: Difficulty of Evaluating Drug Treatment in Surgical Infections, J. A. M. A. 124: 1021-1026 (April 8) 1944.

What are the conditions met by a surgeon that offer the opportunity for employing antibiotics intelligently? These may be classified in two groups—those responding to either prophylactic or active measures.

PROPHYLACTIC USE OF ANTIBIOTICS

Clean Wounds.—The surgeon is interested first of all in preventing infection in operative wounds. All of the minutiae of sterile technique have been developed with that end in mind—the autoclaving of dry goods and solutions, the boiling of instruments, the scrubbing of hands of the operating team, the masking of noses and mouths, the preparation of the operative field, the avoidance of air contamination, the use of silk and cotton for suture material, the gentle handling of tissues, and careful hemostasis. All of these procedures should bring the incidence of wound infection in a clean field to less than 2% and in serious infections to less than 1% in any well-run operating room.

What place have antibiotics in the prophylaxis of infection in clean wounds? Should 50 patients receive an antibiotic or a combination of antibiotics to prevent infection in one of them? No! It is our belief that antibiotics should not be used with clean fields except for certain categories that will be mentioned below. To use antibiotics in clean operations is an admission that the sterile technique in the operating room is not up to the requirements, and it is likely to drop to still lower levels if breaks in technique are not corrected because the surgeon will say, "Oh, never mind. An antibiotic will take care of that."

There are, however, certain cases in which, if infection occurs, it is a very serious matter. These are operations on the brain and on the heart. These are often long procedures, and, therefore, the chance of air contamination is increased. In a somewhat lower category, from the point of view of the frequency of infection, are the long plastic procedures on the neck, chest, and breast.

What antibiotics should be used in these cases, and how should they be used? The condition with which the surgeon has to deal is a wound with relatively few organisms on freshly cut surfaces. The ideal treatment is a fine spray of 5 to 10 cc. of the antibiotic into all crannies of the wound during closure. Thus direct contact with contaminating organisms can be obtained. Furthermore, the best antibiotic is one that is bactericidal. By using such an antibiotic the organisms can be killed directly and are given no chance to gain a foothold. They are not merely held in check as they would be by a bacteriostatic agent requiring the bacteria to be destroyed by the body defenses.

TABLE 1.—*Resistance to Penicillin of Coagulase-Positive Micrococcus (Staphylococcus) Aureus**

Year	No. of Strains	% Resistant
1947-1948	286	17.8
1949	228	29.1
1950	269	43.5
1951	293	43.0
1952	290	31.1
1953 (Jan. 1-May 1)	269	22.3

* Recovered from infections treated in outpatient department, Surgical Service, Presbyterian Hospital, New York.

The commonest contaminating organisms in cle operations are the micrococci (staphylococci) from t air and from the skin of the patient. If the operating te: personnel does not adequately mask the nose as well the mouth, another abundant source of micrococci open to the sterile field. The most reasonable antibiot to choose are penicillin, bacitracin, streptomycin, neomycin (table 2). All of these are bactericidal a potent against micrococci. *Penicillin or bacitracin, i concentration of 1,000 units per cubic centimeter,* m be sprayed on the operative field and are preferable streptomycin and neomycin. In recent years, howev with a large percentage of micrococci resistant to pe cillin and with patients becoming increasingly sensitive penicillin, bacitracin is taking on a more important ro Patients are seldom allergic to bacitracin. On brain s faces, bacitracin is much less toxic than penicillin, a this fact makes it preferable as a prophylactic in neu surgical procedures. *For effective local use, streptomy* requires a concentration of 0.5% and neomycin 1%. large fresh wounds, which are to be closed, neomy might prove to have a systemic toxic effect.

TABLE 2.—*Resistance of Coagulase-Positive Micrococcu (Staphylococcus) Aureus* to Various Antibiotics*

Antibiotic	% Resista
Penicillin	22.3
Bacitracin	7.1
Streptomycin	10.0

Neomycin	1.0

* Recovered from infections treated in outpatient department, Surg Service, Presbyterian Hospital, New York, Jan. 1-May 1, 1953.

During the last few years, reports have come fr many sources that micrococci have become increasin resistant to penicillin. Some reports go as high as 60 80%.[2] Our own experience showed this trend duri the first two years of the extensive use of penicillin, t *in 1951 the rise in the percentage of resistant strains ca to a standstill in infections treated in outpatients.* In t *past two years it has fallen again* (table 1). We belie we were the first to call attention to this fact and ha put forward the theory that the phenomenon may be d to the widespread use of bacitracin and the combin tion of chlortetracycline (aureomycin), oxytetracycli (Terramycin) and chloramphenicol (Chloromycetin

Table 2 shows our most recent experience with te for sensitivity and resistance of micrococci to the fi antibiotics that we use oftenest and against which w routinely test every culture that comes to the laborator Table 3 gives a comparison of the action of bacitrac and neomycin against the major strains of organism coming to the Surgical Bacteriological Laboratory fro all surgical services except otolaryngology and derm tology. This shows how bacitracin and neomycin con plement one another for local therapeutic effect.

Antibiotics given systemically are not *usually indicate* in clean fields for, if potent bactericidal antibiotics a

3. Meleney, F. L., and Johnson, B. J.: Clinical Significance of Increasing Resistance of Organisms for the Antibiotics, Surg., Gynec. & Obst. 97:267-276 (Sept.) 1953.

applied to the surface of the fresh wound, any casual contaminating organisms are not given the opportunity to multiply and invade the deeper tissues. When administered systemically, the antibiotic reaches the wound area in very dilute form. If infection develops in spite of the local prophylactic antibiotic, because the contaminating organisms are resistant to the antibiotic used, cultures will determine the nature of the infection and the sensitivities of the causative organisms to some other available antibiotic, which should then be employed.

Contaminated Fields.—There is, however, a real indication for the use of antibiotics prophylactically in contaminated fields of operation. Bacteria on mucous membrane surfaces of the body cannot be destroyed or reduced in number as readily as they can be on the skin. Operations that expose the tissues to contamination from these sources have, therefore, a greater chance of becoming infected. The incidence of infection in these fields may be 20 to 25% in a well-ordered operating room, if antibiotics are not used. It is reasonable to give antibiotics to four or five patients to prevent infection in one. This applies to operations on the eye, ear, nose, throat, mouth, esophagus, stomach, duodenum, jejunum, ileum, colon, vagina, and penis.

* Recovered from infections treated on all surgical services, Presbyterian Hospital, New York, Jan. 1-May 1, 1953.

It must be remembered that the contaminating organisms are different in different parts of the alimentary tract. The organisms most commonly found must constantly be kept in mind, and the appropriate antibiotic or mixture of antibiotics must be used. In fact, in elective procedures, it is best to take cultures from the operative field a few days before operation and to test the sensitivities of the organisms found.

The organisms that commonly contaminate operative wounds made on the nose are micrococci and nonhemolytic streptococci. On the mouth and esophagus they are the nonhemolytic and anaerobic streptococci, and, where there is a chronic pyorrhea, spirochetes and fusiform bacilli. The stomach with normally acid gastric juice often yields sterile cultures because of the acidity of that secretion. When organisms are found in the stomach or duodenum, they are usually the nonhemolytic streptococci, which are able to persist longer than other organisms in the acid environment and often pass into the duodenum. These species are also present in the jejunum, and here the gram-negative rods of the coli group begin to appear and a little further down, the clostridia, including the Welch bacilli. These three groups increase in number and variety from above downward; they are in greatest concentration in the lower ileum. When they pass the ileocecal valve into the colon, they begin to die in great numbers, so that when the stool is passed out of the rectum, although one-third of the mass is made up of bacterial bodies, most of them are dead.

Operations on the stomach and intestine have been carried out for many years through a clean abdominal wall. The operative field is only contaminated when the bowel is entered. Contamination can be minimized by various closed methods of anastomosis, but with the open methods now widely used, contamination varies greatly according to the care taken to prepare the bowel either mechanically or chemically beforehand and the care taken to prevent spillage. In recent years more and more procedures on the alimentary tract are carried out through thoracic or thoracoabdominal incisions, thus exposing the mediastinum and the pleural cavities to contamination. Often leaks from esophageal or esophagogastric anastomoses, duodenal stumps, gastroenterostomies, or enteroenterostomies are attributed to faulty suturing, but it is our contention that contaminating bacteria are oftener responsible for the failure of these anastomoses to heal and this results in leakage. Such leaks are more apt to occur when the anastomosis is above the stomach than when it is below, because the contamination above is from the mixture of mouth organisms that may be particularly numerous and synergistic, especially if mouth hygiene is bad. The next commonest site of leakage is in the lower ileum, because the intestinal organisms there are most numerous and viable.

It is, therefore, the responsibility of the surgeon to use every means available to minimize the contamination of the operative field whenever he is working along the alimentary tract. Mouth organisms may be reduced by dental care preliminary to any operation on the throat or esophagus, but this is not enough because the bacteria can be further reduced or discouraged by the local use of antibiotics. Bacitracin is particularly useful in this region because it is potent against the nonhemolytic streptococci, the anaerobic streptococci, and the spirochetes of the mouth, and it seldom if ever causes any allergic reaction in the mouth. Bacitracin requires the addition of an antibiotic potent against the gram-negative rods for action further along the alimentary tract, and here neomycin seems to serve well. Neomycin is weak against the streptococci and clostridia, but it is potent against most strains of Esch. coli and particularly of Proteus, which is resistant to almost all of the other antibiotics (table 3).

Both bacitracin and neomycin are bactericidal and are compatible with each other. We have demonstrated their synergistic action many times but never antagonism. Tablets are commercially available containing 2,500 units of bacitracin and 25 mg. of neomycin. These may be dissolved slowly in the mouth once every four or six hours to get the maximum effect in the mouth and esophagus or in the stomach. If the effect is desired in the lower intestine, four tablets should be swallowed every four or six hours. As neither of these antibiotics is absorbed, they continue their maximum action all along the alimentary tract. There is no need for fear of any systemic toxic reactions. Often when cultures are taken from the esophagus and stomach and at the site of bowel resection sterile cultures are obtained after the administration of bacitracin and neomycin, as described above, for 48 or 72 hours. We have not seen or heard of either staphylococcic or proteus enteritis following their use in this manner.

Chlortetracycline, oxytetracycline, and chloramphenicol have all been used, and favorable results have been reported. These three antibiotics, however, are often not well tolerated in the mouth and, therefore, are not available for action on mouth organisms. All of them are partially absorbed from the intestine, and the amount available to inhibit the multiplication of organisms in the large intestine is uncertain. Furthermore, they frequently cause gastrointestinal upsets, with nausea and diarrhea, and often make it necessary to discontinue treatment. Oxytetracycline seems to be the least objectionable in these respects, and, if diarrhea does occur, it can generally be controlled. The association of chloramphenicol with aplastic anemia must be kept in mind. It does not seem advisable to us to run the risk of using it when other measures are superior. Monilial superinfections occur in some cases treated with chlortetracycline, oxytetracycline, or chloramphenicol, and the Proteus bacilli and Micrococcus aureus may multiply prodigiously in the bowel. For these reasons we do not consider any of these three so-called broad spectrum antibiotics optimal for this purpose.

Phthalylsulfacetimide (Thalamyd) has been found to be the most effective of the sulfonamides in reducing the number of intestinal organisms, but the preparation of the bowel with it usually requires five or six days, while the combination of bacitracin and neomycin will often give a sterile culture at the operative site in 48 hours. Further studies are necessary to determine whether it is advisable and more effective to combine phthalylsulfacetimide treatment with antibiotics.

Polymyxin B and chlortetracycline have been combined independently with bacitracin with favorable results, but neither polymyxin B nor chlortetracycline has as wide a spectrum over the gram-negative rods as neomycin, which is effective against most strains of the proteus group. Neomycin has been used alone with good reports of its effectiveness, but its weakness against the clostridia and the intestinal streptococci, both hemolytic and nonhemolytic, leaves a gap in the coverage of the intestinal organisms; this gap is closed by bacitracin. Of 29 strains of Clostridium welchii recently tested, all were susceptible to bacitracin but only 10% to neomycin (table 3).

At the time of operation, the surgeon should take a culture from the lumen of the alimentary tract at the site of operation, wherever that may be, so that he will know within 24 hours what organisms, if any, have contaminated the operative field. If any organisms are still viable in the lumen of the gut, the surface of the tissues at the level of operation will be contaminated by these residual bacteria. It is rational to assume that in every case some of the intestinal organisms have contaminated the operative site. In the past, it has been considered adequate in our hospital to apply a mixture of 20 mg. of streptomycin and 5% *p*-aminomethylbenzene sulfonamide (Sulfamylon) in 100 cc. of water to the area of operation within the abdominal cavity, as advocated by Howes.[4] Recently we have advised the addition to this of 20,000 units of bacitracin in 20 cc. of water or sodium chloride solution to give a safer coverage of the intestinal cocci and clostridia.

Penicillin and streptomycin have demonstrated the effectiveness in the treatment of peritonitis due to a mi ture of lower bowel organisms. These may be given afte bowel resections in a dosage of 400,000 units of penicilli and 0.5 gm. of streptomycin twice a day, or bacitraci may be substituted for the penicillin in a dosage of 20,00 units with 0.5 gm. of streptomycin every eight hours t give a wider coverage over the intestinal cocci an clostridia.

If the cultures taken at the operative site yield orga isms resistant to the antibiotics that have been used, change should be made after 24 or 48 hours to the anti biotic or mixture of antibiotics that have been dem onstrated to have the greatest activity against thes particular organisms. Such treatment should be give systemically, if possible.

Before operations on the vagina, cultures should al ways be taken, and the sensitivities of the bacteria foun should be determined. Then, during the operation, th operative field should be sprayed with the antibiotic tha is most potent against the contaminating organisms.

Another important field for the prophylactic use of th antibiotics comprises civilian accident wounds, burn and gunshot wounds. These are all contaminated, usu ally with a mixture of organisms. Dirty accident and gun shot wounds should always be thoroughly debrided an the debrided tissues, blood clot, dirt, and other forei bodies sent to the laboratory for culture so the surgeo may be forearmed with knowledge of which organism are present and their sensitivities should infection develop. Some residual contaminating organisms are alway left on the surface, but they are not deep in the tissues o the wound, if it is less than four hours old. This offer the best opportunity for obtaining close contact of these organisms with some potent bactericidal antibiotics. A combination of bacitracin, 1,000 units per cubic centimeter, and 1% neomycin covers most of the organisms that may be expected in these wounds. The mixture should be sprayed liberally over the surface and into all nooks and crannies. This local application is more important than the systemic use of antibiotics in these cases. It should be remembered that the organisms are on the surface and not in the tissues, unless the wound is four or more hours old.

Wounds of the scalp, face, or hands may be closed after local application of antibiotics. In other areas, the wounds may be left open, tamponed with China silk, and packed with fine meshed gauze wet with the antibiotic mixture. If on the next day the culture report indicates a change in antibiotics, they should be applied. If the cultures show no important pathogens and the wound remains clean, a late primary or early secondary closure may be done. If the cultures reveal important pathogens, the appropriate antibiotic or combination of antibiotics may be used systemically. The wound should then be left open until the pathogenic organisms disappear from it.

---

[4] Howes, E. L.: Topical Use of Streptomycin in Wounds, Am. J. Med. 2: 449-456 (May) 1947.

The contamination of burns is very similar to that of wounds except that the organisms are generally more numerous and are distributed over a larger area. Again it should be remembered that immediately after the burn, the organisms are on the surface only and that this offers the best opportunity for bringing the most potent antibiotics into contact with them. Again cultures should be taken within 24 or 48 hours to determine the organisms with which the surgeon has to deal. A mixture of antibiotics should be applied to the surface as soon as the cultures have been taken and without waiting for the culture report. The antibiotic treatment should be modified later, if necessary, according to the results of the cultures.

The contamination in burns is oftenest due to hemolytic micrococci and hemolytic streptococci and gram-negative rods of the Proteus, pyocyaneus, and coli groups. Because so many micrococci are now resistant to penicillin and because many patients are allergic to it, bacitracin is the most reliable antibiotic for the gram-positive cocci, and bacitracin, together with a mixture of neomycin and polymyxin B, is best for the gram-negative rods. Polymyxin B is added to the mixture in the treatment of burns because it is the best agent against the pyocyaneus, a common contaminant in burns. There is no danger of systemic toxicity from the local application of these drugs. If the areas are to be left exposed, a solution containing this mixture may be sprayed on the surface, or, if the burn is to be kept under pressure dressing for a time (10 days), the antibiotics may be incorporated in a water-soluble base, like carbowax, on an innermost dressing of fine meshed gauze.

One more situation in which antibiotics may be used prophylactically occurs in cases of elective amputation of an extremity for gangrene. Preliminary cultures and sensitivity tests will indicate the most potent antibiotics against the organisms present in the gangrenous lesion. It must be assumed that organisms are moving up the lymphatics to or beyond the level of amputation. It is good practice to take cultures at the level of amputation and then to spray the surface with the antibiotic indicated by the preliminary culture before closing the wound. If the infection is severe and the organisms of particular virulence, the wound should be left open until the results of the cultures from the level of amputation are known. If the cultures are negative, a delayed primary or early secondary closure may be done. If the cultures are positive, local treatment with the antibiotic should be continued and systemic treatment should be instituted because of the probability that the infection has already gone beyond the cut surface.

ACTIVE TREATMENT OF SURGICAL INFECTIONS

It goes without saying that the antibiotics will not be effective in controlling any infection unless the organism is sensitive to the antibiotic used. This sensitivity can be determined only by culture studies in the laboratory. It cannot be done by guesswork. From the previous course of the infection or the area involved, many experienced surgeons may be able to guess the most likely causative species of bacteria, but they cannot guess, with any measure of certainty, the susceptibility of the organisms to any given antibiotic.

The development of resistant strains of the common organisms, first noted by the micrococci against penicillin and recently by other organisms against all of the antibiotics,[5] makes it imperative that these tests be done. It is more important to determine the sensitivities of the organisms than to name or classify the organisms. The blood agar plate method using filter paper disks wet with the proper dilution of the different antibiotics is the simplest and most reliable, and the dilutions can be adjusted so that the results are of real clinical significance. Our laboratory routinely tests the sensitivity of every culture simultaneously against the five antibiotics most commonly used, penicillin, bacitracin, streptomycin, oxytetracycline, and neomycin. A preliminary report may be made after overnight culture. If any organisms are resistant to these five, further studies are made with chlortetracycline, chloramphenicol, polymyxin B, and erythromycin.

Two years ago we sent a brief questionnaire around to the hospitals in the New York metropolitan area to find out whether they had bacteriological laboratories equipped to do aerobic and anaerobic cultures and sensitivity tests.[6] We also asked how often surgeons requested that these tests be done for cases of infection. At that time, the replies clearly indicated that many hospitals did not have these facilities and that, even when they did have them, such tests were seldom requested. It was then the common habit of many surgeons to give penicillin at once and, if that was not successful, to add streptomycin and then one or more of the other antibiotics in turn or all of them together. Then, if there was no response, they might repeat the sequence again. At a medical meeting held at that time, many surgeons present acknowledged their own fault in this regard; some blamed their laboratories.

Today, although we have not repeated the questionnaire, we know that the situation has improved considerably. More and more laboratories have these facilities, and many surgeons now request that these tests be done. Surgeons are becoming educated to the importance and advantage of calling on and relying on the laboratory for these tests. If, however, the question, "How many surgeons routinely demand these tests for cases of infection and are satisfied with the results?" were asked one wonders how many would answer in the affirmative. Certainly sensitivity studies can be done in any laboratory with the basic facilities that every hospital should have. Surgeons should request these tests, but the laboratory should carry them out routinely, whether they are requested or not. This procedure will give the surgeon the proper basis for the choice of the most effective antibiotic in any given case.

CHRONIC AND ACUTE INFECTIONS

There is a great diversity of well-established surgical infections. Among the acute infections are furuncle, carbuncle, cellulitis, superficial abscess, deep abscess, septicemia, osteomyelitis, suppurative arthritis, tenosynovitis, suppurative lymphadenitis, cholecystitis, appendicitis, local peritonitis, diffuse peritonitis, fibrinopurulent peritonitis, and Meckel's or sigmoid diverticulitis. Chronic surgical infections may develop from any acute infection that has not responded to previous treatment. An arbitrary time division between acute and chronic cases is 30 days. Among the chronic infections are ulcers, undermining or simple and with or without vascular insufficiency, lung and liver abscesses, chronic osteomyelitis, tuberculosis, actinomycosis, synergistic infections, such as progressive bacterial synergistic gangrene, fusospirochetal infections following human and animal bites, gangrenous impetigo and amebic infections, chronic ulcerative colitis, terminal or regional ileitis, chronic diverticulitis, and many others.

[5] Eagle, H.; Fleischman, R., and Levy, M.: Development of Increased Bacterial Resistance to Antibiotics: Continuous Spectrum of Resistance to Penicillin, Chloramphenicol, and Streptomycin, J. Bact. **63**:623-638 (May) 1952.

[6] Meleney, F. L., and Johnson, B. A.: Chemotherapy and Antibiotics in Surgical Infections, S. Clin. North America **32**: 387-403 (April) 1952.

It is not necessary to give details of all of these separate clinical entities here, but we may briefly describe some of the principles involved in the employment of the antibiotics and the surgical procedures in the treatment of these conditions. We would like to make a plea for surgeons dealing with infections to be bacteriologically minded and to keep in mind what and where the bacteria are involved in the process and how they can be reached and destroyed by use of both the knife and antibacterial agents. Today surgery may be obviated in many cases, and this is usually to the patient's advantage.

In acute cases, if possible, a specimen of exudate should be taken by aspiration or by incision for smear and culture before instituting any drug treatment. After the culture has been taken, however, drug treatment should not be delayed. An immediate examination and report on the smear will give some hint regarding the nature of the organism. The surgeon must use his judgment as to which antibiotic is most likely to succeed and how it can best reach the organisms. If, on the next day, the culture indicates that his judgment has been correct, the original antibiotic should be continued, but, if the culture indicates a change, that change should be made at once.

In chronic cases, a careful bacteriological analysis should be made before starting treatment because there is usually a mixture of organisms present that have resisted previous antibiotic treatment. In established infections, the organisms are not merely on the surface but deep in the tissues, possibly in thrombosed blood vessels or in the blood stream. In such cases, the local application of the antibiotic may not contact the organisms; the antibiotic should then be given systemically in such doses and at such frequent intervals that it will reach the spreading periphery of the infection. In many established infections, however, local application is sufficient and the antibiotic can be brought into contact with the organisms in much higher concentration than by means of systemic treatment and without any damage to the local tissues. In this respect, the antibiotics such as penicillin, bacitracin, polymyxin B, streptomycin, and neomycin are far superior to the sulfonamides.

The toxic effects of bacitracin given systemically,
which were produced by the early deep-tank metho
manufacture, have largely been overcome. The pre
tions that are now available for parenteral use are e
tive and safe, if given intramuscularly in a dosage o
more than 20,000 to 25,000 units every six or eight h
and if there is a daily fluid intake of at least 2,500
Neomycin cannot be given systemically without fe
toxicity. Polymyxin B can be given safely with due re
to dosage and should be employed in pyocya
septicemia and in resistant cystitis and pyelonephritis
to the same group of organisms, if they are susceptib
it by in vitro tests.

The body cannot develop any immunity against
of the organisms causing surgical infections, but it
against many organisms causing medical infections.
immunity often plays a part in the recovery from me
infections.

It is of interest and of some importance that if
tetracycline or oxytetracycline fails to control the i
tion, the use of the other is not likely to succeed, bec
the susceptibilities of organisms run fairly parallel
these two antibacterial agents. If resistance develo
one of them during the course of treatment, that o
ism is also resistant to the other.[3]

It has been demonstrated that penicillin and bacit
may be injected directly into the center of furuncles
carbuncles and that they often stop the bacterial a
abruptly and check the further spread of the nec
if the causative organism is sensitive. Both of these
biotics seem to hasten the liquefaction of slough, w
of course must be removed either by incision and d
age, by spontaneous discharge, or by absorption.
carbuncles, if there is a narrow zone of induration ar
the necrotic center, injection into the center is suffi
to cause resolution because it permits a certain am
of absorption into the periphery. If there is a wide
of induration and a small central area of necrosis
antibiotic with procaine hydrochloride (Novocaine
butethamine (Monocaine) hydrochloride may be
jected around the periphery with rapid resolution o
process. In the treatment of abscess cavities, the pus
be aspirated and the antibiotic instilled and reaspi
mixed with pus. This procedure should be repeate
and when there is a reaccumulation of pus. Ofte
whole process resolves in three or four days and the
gical procedure of incision is frequently obviate
there is a wide zone of cellulitis or other indicatio
peripheral spread or sepsis, the systemic administra
of the antibiotic is indicated.

In cases of surgical infection caused by the hemo
Streptococcus, the hemolytic Micrococcus (Staph
coccus) aureus, and organisms of the coli, Proteus,
Pseudomonas groups, septicemia may be present;
means that the bacteria may be recovered from the b
stream. In such cases, it behooves the surgeon to see
remove, if possible, or drain the distributing focus,
to give systemically that antibiotic to which the orga
is most sensitive. It is particularly important in case
acute osteomyelitis that the most potent antibiotic
given early, within four days, to prevent the breakd
of the bone and its very unfortunate sequelae.

7. Meleney, F. L.; Johnson, B. A., and Teng, P.: Further Experiences with Local and Systemic Bacitracin in the Treatment of Various Surgical and Neurosurgical Infections and Certain Related Medical Infections, Surg., Gynec. & Obst. 94: 401-425 (April) 1952.

Purulent collections in joints or in the pleural cavity may also be removed by aspiration and the infection controlled by the instillation of penicillin or bacitracin with reaspiration. This may be repeated as often as there is reaccumulation of exudate. Again in such cases surgery may often be obviated.

In well-established infections in operative or accidental wounds and burns, local treatment with the most potent antibiotic or mixture of antibiotics is often sufficient, but, if there is evidence of spread into the deep tissues, antibiotics must be given systemically. With respect to the gram-negative bacilli, the broad spectrum antibiotics are often the most effective.

In what we have said above, it is seen that the availability and effectiveness of the various antibiotics have modified some of our former fundamental principles in the treatment of surgical infections, but acute surgical infections within the peritoneal cavity should still be governed by the same general rules that have been good for a long time, namely, early operation and the removal of the offending focus, if that is possible. Operation gives the surgeon a clear picture of what he is dealing with, and cultures can then determine the nature and susceptibilities of the offending organisms.

In many instances, chronic surgical infections have been inadequately and improperly handled without a proper bacteriological study or without treatment with an antibiotic potent against the causative organisms. One might go as far as to state that today no acute surgical infection should ever become chronic while under the intelligent care of a competent surgeon. In many cases, the surgical procedures have been inadequate, and there may be necrotic tissue still present in the focus of infection. Almost invariably secondary organisms have had an opportunity to get into the area of infection and may be playing a synergistic role. These cases require a thorough study of the bacterial flora in the infected area and tests for susceptibility of all of the organisms found to all of the available antibiotics. Thereafter these patients require the careful application of the most potent antibiotic or mixture of antibiotics both locally and systemically. With some of these chronic infections, that is all that is necessary to turn the tide and start wound healing, but many of these cases first require surgical removal of the necrotic tissue. This is particularly necessary in chronic osteomyelitis, which demands the excision of all of the grossly diseased bone followed by the local application of the indicated antibiotics, preferably those of the bactericidal group. This treatment should be continued daily until healing begins and permits either a secondary closure or a skin graft.

SYNERGISM AND ANTAGONISM

When faced with a fulminating acute infection or a long-standing chronic one, some surgeons give two or three antibiotics as a shotgun remedy without any consideration of bacterial cultures or sensitivity test and without a thought concerning the possibility of antagonism of one antibiotic toward another. The surgeon often excuses himself by saying, "If one antibiotic doesn't stop the infection, one of the others will." This practice is certainly to be condemned as being unscientific, usually ineffective, and often harmful.

When primary cultures and sensitivity tests show a single organism and a single potent antibiotic out of five or more tested, that antibiotic should be used alone. If there is a mixture of organisms, as is so often the case in chronic infections, the susceptibility of each one should be tested and the most potent antibiotic used against each organism provided the antibiotics are not antagonistic to one another. If none of the antibiotics is effective by routine tests, the concentration can be increased in liquid mediums and the minimal inhibiting concentration can be determined. At times synergism of two antibiotics may be demonstrated by combining fractions of each of the minimal inhibiting concentrations. We believe that one criterion for demonstrating synergism should be that one-fifth plus one-fifth (or less) of each of the minimal inhibiting concentrations causes inhibition of growth. The two antibiotics may be said to have a synergistic action. If one-half plus one-half of the minimal inhibiting concentrations causes inhibition, it is considered an additive effect. If the combination requires more antibiotic for inhibition than the minimal inhibiting concentration of each one alone, there is antagonism.

The terms synergism and antagonism have been used for many years. In 1948, Eagle and Fleischman reported the remarkable synergistic action of penicillin and bacitracin in syphilis in experimental rabbits.[8] We have demonstrated, and reported in 1950, both in vitro and in vivo synergism of penicillin and bacitracin.[9] Jawetz and his co-workers have recently made many laboratory and clinical observations on this subject.[10] They find that synergism often exists between two of the bactericidal, or group 1, antibiotics (penicillin, bacitracin, streptomycin, polymyxin B, and neomycin) and between antibiotics of the bacteriostatic, or group 2, antibiotics (chlortetracycline, oxytetracycline, and chloramphenicol). However, antagonism often results, if a member of group 2 is combined with a member of group 1. This does not always hold true and cannot be predicted with certainty. It depends a great deal on the susceptibility or resistance of the organisms.[11] However, it should be kept in mind when antibiotic combinations are used clinically. Combinations of the two groups should be avoided unless synergism has been demonstrated in vitro. Further study is required on this important problem, and it will need to be continued as new antibiotics become available.

SUMMARY AND CONCLUSIONS

The natural course of surgical infections may be profoundly altered or brought to a complete standstill by the use of the appropriate antibiotic or combination of antibiotics in addition to the proper surgical procedure. Many times surgery may be completely obviated or its extent curtailed.

Successful treatment requires, on the part of the surgeon, the knowledge of the natural occurrence of bacteria in relation to the body, their potentialities and predilections, their behavior after gaining a foothold in the body, and the proper methods and timing of certain surgical procedures. Of equal if not greater importance for success in treatment is a knowledge of the causative and associated organisms and their susceptibility to the available antibiotics and the proper methods for their application. Our recent experience in the use of antibiotics and surgery in the treatment of surgical infections is outlined.

PHARMACOLOGICAL TREATMENT OF AGED PATIENTS IN A STATE MENTAL HOSPITAL

Sol Levy, M.D., Spokane, Wash.

Improvement in medical care and general living conditions has definitely lengthened the average span of human life. Each year a greater percentage of the population reaches advanced ages, and statistics indicate that this trend will continue. Consequently there are constantly increasing numbers of persons subject to degenerative changes, especially in the central nervous system. Therefore, there has been an ever increasing demand for admission of aged patients to private and public mental institutions, and at the present time more than one-third of all persons first admitted to public mental hospitals in the United States are over 65 years of age. The magnitude of the important problem posed by this group needs no further emphasis, but it becomes even clearer if one considers that, for each person whose condition requires care in a mental hospital, there must be several others who can be cared for at home and who are not admitted to such a hospital. Out of necessity, therefore, extensive interest has been created in the problem of the aged patients, and consequently much attention has been given to the emotional problems of the aged and the aging, and new methods and ways are being found to deal with them.

In certain of these aged persons, impairment in the central nervous system is severe enough to produce serious emotional disturbances, paranoid delusions, advanced deterioration, and difficult behavior problems. These patients undoubtedly need and deserve the protection and the modern psychological and psychiatric treatment methods that are provided in an up-to-date psychiatric hospital.

Recently much progress has been made in the treatment of psychotic reactions in the aged. The previously held attitude of therapeutic nihilism for this group was based on the erroneous belief that senile organic changes described as both progressive and irreversible were the sole causes of the mental symptoms. This belief has been entirely abandoned, since more recently pathological studies have shown that there is no direct correlation between the intensity of mental symptoms and the severity of the pathological changes. In fact, many of the patients with the severest neuropathological changes were found to be free of mental symptoms during their lifetime, as reported by Rothschild [1] and others. Furthermore, attention was drawn repeatedly to the high incidence of so-called functional types of psychotic reactions that first developed late in life and that were not the result of irreversible pathological brain changes. It was also found not to be uncommon for major mental disorders to occur first in old age. Clow,[2] for instance, among 100 patients with psychosis accompanied by cerebral arteriosclerosis, found 61 who had previously in their adult years showed more or less minor symptoms of mental illness characterized mainly by sexual maladjustment and psychopathic behavior. This, then, resulted in a new therapeutic approach. In addition to other psychological and physiological methods, convulsive therapy is being more and more utilized in the treatment of aged psychotic patients, after having been proved to be a relatively safe and successful procedure. An increasing number of favorable reports of this therapy have appeared in the literature, among them reports by Robinson,[3] Bennett,[4] Wilbur and Fortes,[5] and more recently by myself.[6]

On the other hand, however, the majority of these aged patients show only mild memory defects, slight confusion, and the somewhat more exaggerated deterioration characteristic of the aging process. Their medical care and disposition presents much more complicated problems than those of the aforementioned group, and unfortunately are not solved adequately at the present time. Although the public mental hospitals have been called on to care for an increasing number of such older patients, this group of elderly patients presents a problem in itself within the institution. It has been shown, for instance, that in the state hospital these patients individually do not present any burden, but rather do collectively because of the ever increasing number of them admitted. Their individual prognosis is definitely poor, for very few of these patients can ever hope to be discharged, and within the first 12 months almost one-half of them have died. In fact, the highest death rate occurs within the first month of admission, in spite of the fact that on admission their physical health is good and average for their ages, and in spite of the probably much better medical and nursing supervision than a person of that age could expect in his own home or even in a nursing home or county farm. They are, however, as has been shown, called upon to make an entirely new emotional adjustment in a strange environment. The adjustment at this age, because of their limited mental capacity for grasping new situa-

Clinical Director, Eastern State Hospital, and Clinical Affiliate in Psychiatry, University of Washington Medical School, Seattle.

Read before the Section on Nervous and Mental Diseases at the 102nd Annual Meeting of the American Medical Association, New York, June 4, 1953.

Because of space limitations, the bibliographic references have been omitted from THE JOURNAL and will be included only in the author's reprints.

tions, seems almost impossible. A vicious cycle is thus set in motion as they become more emotionally disturbed and that in turn there is a detrimental, almost fatal, effect on their physical health.[7]

Thus, during recent years, various studies have appeared in the literature dealing with newer methods of treatment for this group. The methods include, to name a few, the possibility of home care for the aged, the creation of special institutions, the improvement of nursing care, the application of newer psychological treatment methods, meeting of dietary requirements, and finally therapy with various drugs.

The role of anoxia in disease is being recognized more and more, and since it has been found that the brain is also particularly sensitive to oxygen lack, it is not surprising that anoxia may lead to mental disturbances. Houston [8] in 1949 stated, "The mental signs of anoxia may be subtle and easily mistaken for primary neurologic disease. Mental confusion, emotional lability, errors in judgment, inability to concentrate, headache, or gross tremors are frequently caused by oxygen lack alone and may be a principal evidence of its presence. These signs and symptoms are often seen in elderly persons with arteriosclerosis, in patients with chronic pulmonary disease, anemia, carbon monoxide poisoning, and other conditions that cause chronic low-grade, tissue anoxia." Freyhan and co-workers,[9] using the nitrous oxide technique, studied cerebral blood flow and cerebral metabolism in patients with senility and cerebral arteriosclerosis. They concluded that their data as a whole strongly suggest that the senile psychoses, including those associated with cerebral arteriosclerosis, are associated with and are probably the result of a significant reduction in cerebral oxygen utilization caused by increased cerebrovascular resistance and the resultant significant reduction in blood flow through the brain. However, it should be mentioned at this point that elderly, nonpsychotic persons also have relative cerebral anoxia and that no correlation could be made between readings obtained and mental symptomatology.

Consequently, a great deal of importance was attached to cerebral anoxia as the factor responsible for the mild mental symptoms in the aged, and various therapies were introduced with the ultimate goal of correcting this factor. On the basis of experimental work with respiratory enzymes, it was found that cytochrome C, for instance, might be employed in the problems of tissue anoxia, acute and chronic, and to meet many cellular needs, especially during attempts at regeneration of nerve cells. It was argued that these conditions would seem to be outstanding in the presenile and senile brain, with or without arteriosclerosis, where ganglion cells undergo the typical changes of involutional atrophy and degeneration with interactions of parenchyma and neuroglia that are subject to much variation. On the basis of this reasoning, Garnett and Klingman [10] in 1949 reported the results of a biochemical experiment with cytochrome C in 17 patients with presenile, senile, arteriosclerotic, and involutional states. Their results showed that, of the 17 patients observed, 11 were thought to show clinical improvement and 6 to show none during and after injections of cytochrome C. The clinical improvement in their series was noted in a majority of cases in regard to memory, orientation, irritability, interest, confusion, and behavior. They observed only slight changes in the electroencephalographic recordings and stated that these changes may be insignificant. Psychometric examinations showed qualitative improvement in keeping with clinical improvement and a trend toward higher scores. On the other hand, Forster [11] in 1951 reported the results of treatment with cytochrome C in cases of senile and arteriosclerotic dementia and stated that it was not possible to demonstrate any significant improvement in the treated group compared to the control group that received injections of normal saline solution.

Pentylenetetrazol (Metrazol), a synthetic organic tetrazole compound, has long been effective in respiratory and circulatory stimulation. Pharmacologically it is said to exert an intense stimulating action on the central nervous system. It acts primarily on the higher centers of the brain, particularly on the respiratory, vasomotor, and vagal centers of the medulla, but all parts of the cerebrospinal axis are stimulated to some degree. Its analeptic action is said to be most evident when the higher centers are depressed owing to narcotic drugs, including the barbiturates and alcohol, or to illness or to old age.[12]

On the basis of these facts, Chesrow and co-workers [13] argued that "one might expect that metrazol by stimulating the respiratory center in the aged would improve pulmonary ventilation and indirectly the circulation and so help to overcome the anoxia frequently present in the aged, the depressed and the fatigued. At the same time the analeptic action of the drug and its ability to increase nerve impulse transmission should act as a general tonic so that the patient might well have an increased sense of well-being, be less depressed and perhaps also less confused." They gave pentylenetetrazol orally in arteriosclerosis associated with senility and selected for their study 32 cases of advanced arteriosclerosis with definite evidence of mental confusion. Pentylenetetrazol was given orally in an average dose of 1 or 2 tablets four times a day, and the authors reported excellent results in 4 cases, marked improvement in 8, fair improvement in 10, some improvement in 4, and no improvement in 6 cases. They concluded that "judging from this rather small series of cases metrazol is an effective and safe analeptic and of definite value in geriatric practice." Similar favorable results with the oral use of pentylenetetrazol were reported by Fong [14] at the gerontological meeting in September, 1952, at Washington, D. C. Dr. Fong chose very disturbed, almost psychotic patients, and 48% of them showed definite improvement, especially in becoming more amenable to ward discipline. Suter [15] and Linden and Courtney [16] were also able to confirm the beneficial effects of pentylenetetrazol given orally to mentally confused persons. More recently Swenson and Grimes [17] reported on the oral use of pentylenetetrazol, especially as it affects behavior, in 25 hospitalized patients. They found no statistically significant differences in a comparison of the pretreatment and post-treatment rating, but stated that subjective reports of patients and ward personnel indicated that certain observable changes may have occurred. Some of the patients receiving pentylenetetrazol slept better, were more active on the ward, and displayed less antisocial behavior. They claimed that further study using different rating techniques and larger doses of pentylenetetrazol seems indicated.

Following the successful use of nicotinic acid in relieving mental symptoms of pellagra, this drug soon was applied in the treatment of a number of psychiatric syndromes, particularly organic psychoses of varied etiology. Cleckley, Sydenstricker, and Geeslin [18] obtained beneficial results from the use of nicotinic acid in a group of patients with organic psychoses who showed no typical signs of pellagra but did present some evidence of malnutrition. Later Sydenstricker and Cleckley [19] reported that nicotinic acid had proved effective in the treatment of another group of patients with organic psychoses, two-thirds of whom were in the senile or presenile age range and in none of whom was there any suspicion of pellagra. On the basis of their studies, these workers concluded that a therapeutic trial with nicotinic acid was indicated in confusional psychosis attributed to cerebral arteriosclerosis or senility, or in toxic psychosis, exhaustion delirium, and other confusional psychoses of doubtful etiology. More recently Caldwell and Harwick [20] and Lehmann,[21] among others, expressed the opinion that nicotinic acid is of value in the treatment of organic psychosis attributed to cerebral arteriosclerosis or senility. The rationale of this treatment is based upon the now generally accepted hypothesis that nicotinic acid may produce its beneficial effect in many confusional states by means of cerebrovasodilatation, as originally advanced by Moore [22] and Aring and co-workers.[23] More recently, however, Scheinberg [24] exploring other scientific techniques of investigation, concluded that nicotinic acid does not cause cerebral vasodilatation. It was also argued that many aged persons also have evidence of deficiency of nicotinic acid so that they can benefit from its administration. More recently Gregory [25] determined the efficacy of nicotinic acid in psychoses of senility. He studied 54 patients and found that the prognosis with nicotinic acid therapy appears to be correlated with age; the younger the patient the better his chances of recovery. He found that marked improvement occurred in about 50% of patients under 65 years of age and in only about 10% of those over 65 years of age. He also stated that nicotinic acid is most beneficial in confusional states and psychoses of recent onset, and that it must be administered promptly because reversible changes in cellular function are followed quite rapidly by irreversible structural changes. Thus, on the basis of this study, Gregory suggests that nicotinic acid may be of more benefit in prophylaxis than in cure, since according to him some deficiency of nicotinic acid is believed to be one of the etiological factors involved in the development of psychoses in the aged.

Histamine, because of its vasodilatory properties, has also been used in cases of cerebral arteriosclerosis with the hope of improving the cerebral circulation; however, Taylor [26] was unable to produce any beneficial changes with its use. More recently Moore and co-workers [27] reported on the combined histamine-nicotinic acid therapy and claim excellent results with this method. They stated, "We believe intravenous histamine-nicotinic acid dilation therapy actually improves the function of physiologically impaired or non-functioning brain cells. Whether this is a result of increased cardiac output, increased vasodilatation of cerebral vessels, increased capillary permeability, or an actual physiological action on the cells we do not know." They claim that 23 of 24 patients were greatl improved; 21 were able to leave the hospital, many o them being engaged successfully in various types of worl

Tolazoline (Priscoline) given in 25 mg. doses for times daily for four weeks has also been employed in th treatment of confusional states and psychotic reaction among the aged.[28] However, the report indicates that th psychotic symptoms of patients receiving tolazoline were not benefited by the medication.

Of the other pharmacological treatment methods ap plied for the mildly confused and deteriorated aged, ad ministration of steroid hormones has been used with mor or less success.[29] Other methods include stimulatory drug such as *dl*-amphetamine sulfate (Benzedrine), *d*-ampheta mine sulfate (Dexedrine), caffeine and ephedrine, as we as the various vitamins and proteins. However, all thes produced little, if any, improvement.

The present study, then, concerns itself with the phar macological treatment of the aged, particularly those wit only memory defects, confusion, and deterioration in th absence of more serious emotional and psychiatric dis turbances. This study was undertaken with the aim o finding a therapeutic regimen for this large group of insti tutionalized patients that is not only practical but als simple and safe. For this reason stimulatory, vasodilatory and enzymatic drugs were investigated.

MATERIAL AND METHOD

Thirty male patients were used in this study, and thes patients served as their own controls. Their ages range from 61 years of age to 88 years of age, the average ag being 74 years. The patients were selected because of th presenting clinical picture of marked memory defec confusion and deterioration, and mild behavior disorders but without overt symptoms of serious emotional an psychiatric disturbances. These patients fall into variou diagnostic categories, more than two-thirds having a diag nosis of either arteriosclerosis or senility. The exact diag nostic classification of the 30 patients is as follows:

Chronic brain syndrome associated with arteriosclerosis with behavioral reaction	12
Chronic brain syndrome associated with senile brain disease with behavioral reaction	8
Chronic brain syndrome associated with senile brain disease associated with psychotic reaction	1
Chronic brain syndrome associated with circulatory disturbance with behavior reaction	2
Paranoia	1
Paranoid state	1
Schizophrenic reaction, paranoid type	4
Manic depressive reaction, depressed type	1
Total	30

As can be seen, some of the patients fall within the diagnostic classification of functional disorders such as schizophrenia of long-standing. These were purposely included because in most of them the so-called senile changes overshadowed their original mental disturbances, and their overt behavior was entirely in correspondence with their aging process and not with the symptomatology of their original mental disorder. The average length of stay in the hospital of this group of patients was 7 years, with the shortest stay 9 months and the longest over 40 years.

Cytochrome C parenterally, pentylenetetrazol orally, nicotinic acid orally, either alone or in combinations of two or three, and placebos identical in appearance and given by the same route were administered to the same group of patients. Cytochrome C was administered according to the method described by Garnett and Klingman. After a negative skin test, 1 cc. of cytochrome C was given intravenously. On the following day 2 cc. were given intravenously, on the third day 3 cc., and thereafter 5 cc. daily for a total of 15 days. Pentylenetetrazol, on the other hand, was given orally in tablet form, the dose being two tablets three times a day, or a 24-hour total of 9 grains (0.6 gm.) for a period of 30 days. Nicotinic acid was also given orally, the dosage being 100 mg. three times a day for 30 days. Placebos identical in appearance and administered by the same route were given for a period of three weeks in between the various courses of drug therapy. It was then decided to combine the various drugs, and for 21 days the patients were given an elixir of pentylenetetrazol and nicotinic acid. This elixir per drachm contained 3 grains (0.2 gm.) of pentylenetetrazol and 100 mg. of nicotinic acid in a vehicle of compound pepsin elixir. One drachm of the elixir was given three times daily. In other words, each patient received 0.6 gm. of pentylenetetrazol and 300 mg. of nicotinic acid in a 24-hour period. Finally, for a period of 21 days 5 cc. of cytochrome C were given daily in addition to the daily dose of elixir containing pentylenetetrazol and nicotinic acid.

Complete physical and neurological examinations, electroencephalograms, chest roentgenograms, complete blood counts, urinalyses, and determinations of the sedimentation rate, the nonprotein nitrogen, creatinine, icteric index, lactic acid, and fasting blood sugar were done prior to the start of the investigation, at the end of each period of drug as well as placebo administration, and following the termination of the investigation. Psychometric examinations using the verbal scale of the Wechsler-Bellevue, both forms 1 and 2, as well as electroencephalographic tracings were made at the same intervals. The chest roentgenograms were interpreted by the consulting roentgenologist, electrocardiograms by the consulting cardiologist, and the electroencephalograms by the staff encephalographer. Psychometric examinations were conducted by graduate students of the department of psychology of Washington State College, Pullman, Wash. None of these interpreters had any knowledge of the type or amount of therapy being administered to these patients. Daily clinical observations were made by the psychiatric aides, and they were recorded on a revised Malamud-Sands Worchester Rating Scale. The original Worchester Rating Scale was used by the supervisor, who checked the patients' behavior twice weekly, and also by the ward physicians, who checked the patients' behavior once weekly. These observers were aware that this particular group of patients were subject to an experimental investigation; none of them, however, had any knowledge of the type or amount of therapy being given. It should also be mentioned that these patients remained in the same ward environment as their fellow patients who did not participate in the study, and their daily routine during the testing periods was the same as previously. No other medicament except an occasional sedative at bed time was administered.

The original Worchester Rating Scale as modified by Malamud and Sands was modified for use by the psychiatric aides. Of the 19 points to be checked on the original scale, only 12 of these were utilized by us in a simplified form as shown in table 1.

Originally the study was started with 30 patients, but one of the patients died suddenly of coronary occlusion during the investigation, so that the study was completed with only 29 patients. Psychological testing could be carried on in only 24 of the 29 patients and in only 20 of the 29 patients was it possible to obtain a complete series of satisfactory electroencephalographic tracings. The daily, twice weekly, and weekly observations as well as the laboratory tests, chest roentgenograms, and electrocardiograms were made on the complete series of 29 patients.

TABLE 1.—*Revised Malamud-Sands Worchester Rating Scale**

Appearance	Neat Careless
Personal Habits	Able to Attend to Needs Has to be Assisted
General Activity	Active Quiet
Sociability	Mixes With Others Does Not Mix
Attention	Alert Dull or Indifferent
Mood	Elated Even Depressed
Feelings	Too Sensitive and Irritable Easy Going Too Indifferent
Speech	Spontaneous Uncommunicative
Memory	Good Fair Poor
Work	Willing Disinterested

* One factor for each category was to be checked; that is, the factor that most closely described the patient and his activity.

RESULTS OF STUDY

The results of this study are summarized in table 2. From this table it can be seen that the most important changes occurred following the administration of the elixir containing pentylenetetrazol and nicotinic acid. This elixir produced a marked improvement in the behavior of the patients as seen on the rating scale, a better performance on psychological tests, an improvement in the physical health of the patients through gain in weight, and restoration to normal of previously abnormal lactic acid values of the blood. In addition, some of the electroencephalograms that were abnormal at the beginning of the study returned to normal. Other important findings shown on this table indicate that, following administration of cytochrome C, there was a drop in the blood count and hemoglobin that produced a mild to moderate secondary anemia; also the behavior of these patients as seen on the revised Malamud-Sands Worchester Rating Scale seemed slightly deteriorated as compared to the basic evaluation. On the other hand, following the administration of (1) pentylenetetrazol orally, (2) cytochrome C (3) nicotinic acid orally, (4) the combination of cytochrome C plus the elixir of pentylenetetrazol and nicotinic acid, and (5) the administration of placebos, no significant clinical or laboratory changes occurred.

The influence of the various drugs on the different behavior characteristics, as seen on the revised Malamud-Sands Worchester Scale, is shown in table 3. It should be mentioned here that the scoring of all three independent observers corresponded in about 85% of the cases, so that the findings given on table 3 are the pooled results of these independent observations. From this table it can be seen that the improvement in the rating scale following administration of the elixir of pentylenetetrazol and nicotinic acid was present in almost all checked factors, while the other drugs produced no or very variable and only insignificant changes.

The chart indicates the percentage of patients showing improvement in each of the 12 behavior factors following the administration of the elixir of pentylenetetrazol and nicotinic acid. It can be seen from this chart that the greatest improvement occurred in what is described as feelings. Seventy per cent of the patients who were previously described as too sensitive or irritable became easy going following the administration of the elixir. Fifty-two per cent of the patients who previously did not mix well with others became more sociable and mixed well with other patients. After this treatment 48% of the patients who previously had to be assisted with their personal needs were able to take care of their personal hygiene and to attend to their personal needs alone. In general appearance 41% improved, and they became neat while previously they were careless. Thirty-eight per cent became more alert, and 31% showed improvement in both memory and general activity. The factors least affected were what is described as interest in work and eating habits; only 14% of those who had been feeding problems improved and were able to feed themselves spontaneously.

Lactic acid values, which were abnormal in over 85% of this group before the investigation was started, became normal in all but one of the patients following the administration of the elixir. This might be due to the improvement in behavior that resulted in greater activity and thus indirectly affected the circulatory system. On the other hand, only slight and insignificant changes occurred in the lactic acid values after the administration of pentylenetetrazol, the elixir of pentylenetetrazol and nicotinic acid, and cytochrome C. After the administration of the elixir of pentylenetetrazol and nicotinic acid, all patients subjectively stated that they felt much better physically and this was objectively confirmed by the gain in weight ranging from 2 to 8 lb. (907 to 3,629 gm.) in over 75% of the patients. On psychological examinations with the Wechsler-Bellevue there was an average gain of 6 points in the intelligence quotient following the administration of the elixir of pentylenetetrazol and nicotinic acid. This gain was probably due to the increase of attention and improvement of feelings of the patients. They were able to concentrate better on the tests and took more interest in them. This gain becomes even more marked when this group of patients was divided into those suffering from long-standing functional psychoses such as types of schizophrenic reactions and those suffering from cerebral arteriosclerosis or senility. In the latter group, the so-called organic group, there was an average improvement in the intelligence quotient of 9 points, while the so-called functional group showed only an average improvement

† The elixir of pentylenetetrazol and nicotinic acid.

of 2 points. This might be due to the fact that in the functional group deterioration had occurred because of the long duration of the illness that seemed to a certain point irreversible.

As mentioned previously, a complete series of satisfactory electroencephalographic tracings was obtained on only 20 patients of this group. Thirteen, or 65%, of these tracings were considered normal and were not affected by any of the drugs and placebos. This is approximately the same incidence of normal electroencephalograms among arteriosclerotic and senile persons as has been reported in the literature.[30] Seven, or 35%, of the total were abnormal. Three, or 15%, of the total group, or 43% of the abnormal electroencephalograms became normal following the administration of the elixir of pentylenetetrazol and nicotinic acid, while four remained unchanged. The abnormalities in these three tracings, which were of the paroxysmal type, disappeared following the administration of this elixir.

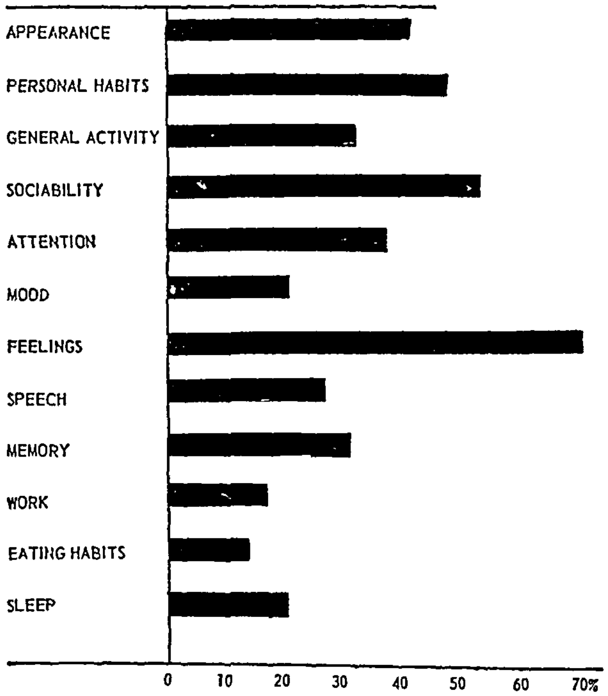
No correlation could be made in regard to the age of patients; in other words, the improvement obtained following the administration of the elixir was present regardless of the age of the individual patient. This would be somewhat in variance with the findings of Gregory,[25] who found that the improvement with nicotinic acid is closely related to the age of the patient. However, it should be mentioned that this author used nicotinic acid alone and not in combination with pentylenetetrazol.

SUMMARY AND CONCLUSION

The value of various stimulatory, vasodilatory, and enzymatic drugs in the treatment of aged persons hospitalized in a state hospital for the mentally ill was studied. It was found that the greatest improvement for this type of patient was obtained with a combination of pentylenetetrazol (Metrazol) and nicotinic acid. These drugs were combined in an elixir containing per drachm 3 grains (0.2 gm.) of pentylenetetrazol and 100 mg. of nicotinic acid with compound pepsin elixir as the vehicle. It was given in doses of 1 drachm three times a day. This elixir produced physical improvement in the patients both objectively and subjectively, produced a marked improvement in their behavior and a better performance on psychological testing with an increase in the intelligence quotient, restored to normal previously abnormal blood lactic acid values, and restored to normal some of the previously abnormal electroencephalographic tracings. Cytochrome C on the other hand, which previously has been said to be of value for this type of patient, has not shown beneficial effects, at least in the doses administered in this study. In fact, it was found that, after administration of cytochrome C, there was not only a slight deterioration in the patients' behavior but also a tendency toward secondary microcytic anemia.

On the basis of this study it is, therefore, felt that the combination of pentylenetetrazol (an analeptic) and nicotinic acid (a vasodilator) is of value in the treatment of aged patients hospitalized in an institution for the mentally ill. It is particularly helpful for those with only mild memory defects, confusion, and deterioration in the absence of more serious emotional and psychiatric disturbances. It seems especially helpful in combating symptoms of abnormal behavior, and those are the symptoms that are most objectionable to the family members and relatives. On the other hand, symptoms pertaining to intellectual impairment are not combated so effectively with this combination of drugs. This might be due to the fact that intellect and memory are first to suffer, while personality and behavior changes occur later. Thus it may be assumed that the former phenomena depend on more definite organic changes that may be irreversible, while the latter symptoms, those dealing with impaired behavior, to some extent may still be reversible.

This combination has proved safe and simple as well as practical and inexpensive, and thus can be used without hesitation on an ambulatory basis. With its use it should be possible to ease the burden of caring for the mildly confused and mildly deteriorated aged patients in public and private psychiatric institutions. Thus a smaller proportion of hospital personnel and budget would be needed for what previously amounted only to custodial care of this group of patients. This saving would eventually enable the mental hospital to return to its primary function, namely, the treatment and rehabilitation of younger mentally ill patients, instead of becoming a purely custodial organization for the aged. Since many of the aged persons studied showed only the commoner evidences of simple deterioration, only modification of the conditions for which this elixir has proved successful was required. Many of these patients, with the aid of this elixir, or possibly similar acting drugs would therefore not inevitably have to be committed to psychiatric institutions and could be permitted to live in the community with safety and without harm to others.



Percentage of patients studied in whom changes according to the Revised Malamud-Sands Worchester Rating Scale were observed.

ERYTHROMYCIN IN LOCAL TREATMENT OF CUTANEOUS BACTERIAL INFECTIONS

Clarence S. Livingood, M.D., Elizabeth S. Head, M.T., Edwin A. Johnson, Ph.D.
and
Samchai Nilasena, M.D., Galveston, Texas

Erythromycin, discovered by McGuire and his associates [1] in 1952, is a new antibiotic produced by a micro-organism (identified as a strain of Streptomyces erythreus) that was isolated from a soil sample collected on the Island of Panay, Philippine Islands. This antibiotic is white, crystalline, soluble in water to the extent of about 2 mg. per milliliter, and highly soluble in some organic solvents, such as alcohol and acetone. It is a basic compound with an empiric formula that is thought to approximate $C_{39}H_{73}NO_{13}$; there is no benzene ring structure in the formula. Stability data indicate that the dry crystalline compound is stable at room temperature for at least a year, but solutions of the antibiotic are comparatively unstable. The best stability is achieved with low temperature and neutral pH. At room temperature with a pH of 7, 86% activity remained after a storage period of 24 hours, whereas no activity remained after the same period of time with a pH of 4.[2]

Erythromycin is effective by mouth, and currently this is the only systemic route of administration. The recommended dosage schedule for adults is from 300 to 400 mg. every eight hours and for children from 6 to 8 mg. per kilogram of body weight every six hours.

The original pharmacological investigation of the drug by McGuire and co-workers [1] indicates that erythromycin has a comparatively low toxicity in animals and does not affect parenchymatous organs significantly. There was no evidence of eighth nerve damage in these animal experiments. To date there has been no report of serious side-effects when erythromycin was administered to patients with various types of systemic infections, although mild gastrointestinal symptoms have been noted in some cases.[3] These symptoms, which include nausea, vomiting, diarrhea, or abdominal cramps, seem to be du to a direct action of the drug on gastrointestinal motilit

The laboratory work of McGuire and his associates Haight and Finland,[4] Heilman and his associates,[3a] ar the laboratories of the pharmaceutical houses that pr duce this antibiotic indicates that erythromycin is a wi range antibiotic with particular activity against gran positive organisms, whereas the coliform and enter gram-negative bacilli are resistant. The list of sensiti organisms includes various types of Pneumococcu groups A to G of Streptococcus hemolyticus, some strai of nonhemolytic streptococci, staphylococci, Corynebac terium diphtheriae, Clostridium tetani, Cl. perfringen Cl. septicum, Bacillus anthracis, Listerella monocyt genes, Hemophilus pertussis, Pasteurella tularensi Neisseria gonorrhoeae, and certain rickettsias and larg viruses. The list of resistant organisms includes Esch richia coli, Aerobacter aerogenes, Proteus vulgari Pseudomonas aeruginosa, and Salmonella typhosa.

The first clinical reports on the systemic administr tion of erythromycin for the treatment of various typ of infections were those of Heilman and his associates, and Haight and Finland.[3b] They reported that it wa particularly effective for the treatment of pneumococc pneumonia and hemolytic streptococcic infections suc as pharyngitis, tonsillitis, carbuncles, cellulitis, an erysipelas. These clinical results corresponded to th impressive in vitro effect of the antibiotic for the etiolog cal agents of these diseases. It is of particular intere that strains of streptococci and staphylococci that wer resistant to other antibiotics (penicillin and the broa spectrum antibiotics) were found to be as sensitive t erythromycin as the nonresistant strains.

The study here reported concerns the evaluation c erythromycin as a topical therapeutic agent. We hav observed a series of 184 patients with various types c cutaneous bacterial infections, all of whom received loca treatment with the antibiotic. We have had some experi ence with the oral administration of erythromycin i patients with extensive cutaneous bacterial infections but this will not be included in this paper. The results o in vitro tests with erythromycin and other antibiotics o numerous strains of the two bacterial organisms (Micro coccus pyogenes var. aureus, and beta hemolytic strepto cocci) that are of particular importance in cutaneous bacterial infections will be reported, and an attempt will be made to correlate these data with clinical results.

METHOD OF TREATMENT

All but a few of our patients were treated with some type of ointment preparation, the exception being the use of compresses or soaks of an aqueous solution of 0.5 mg. of erythromycin per cubic centimeter of water. Because of our previous experience with the topical

application of other antibiotics, we decided to use a concentration of 5 mg. of the antibiotic per gram of ointment base, although a few patients were treated with 1% erythromycin ointment (10 mg. per gram in petrolatum). In 44 of these patients, a combination of 5 mg. of erythromycin and 5 mg. of neomycin sulfate per gram of ointment base was either the only local treatment or the effect of this combination was compared with the plain erythromycin ointment. Another variable that was introduced in the ointment used for some patients was the addition of moniliostatic agents (0.2 mg. of methylparaben-U. S. P., and 1.8 mg. of n-butyl *p*-hydroxybenzoate per gram of ointment base). The ointment bases that were used included (1) white petrolatum, (2) a wool fat-petrolatum base, (3) a cholesterol-petrolatum base, and (4) Aquaphor (a hydrophilic ointment containing hydroxyl animal fats). We did not use erythromycin in a water-miscible base because of the instability of the antibiotic under these circumstances.

The patients were instructed to apply the ointment either two, three, or four times daily. In some cases, the application of the ointment was followed by bandaging of the part (usually with Surgitube gauze), and in these patients the bandage was changed twice daily. Removal of crusts and other forms of local débridement were not emphasized, and the patients were not instructed to carry out cleansing of the affected parts; this routine was followed only because we attempted to avoid as many variable factors as possible. When possible, the erythromycin preparation was applied to the lesions on one affected site, and the plain ointment base to lesions at another site; the distribution pattern and other factors made it impossible to carry out this controlled experimental approach in the majority of patients. The fact that some of these patients had had previous ineffective topical and systemic therapy served as a control in other cases.

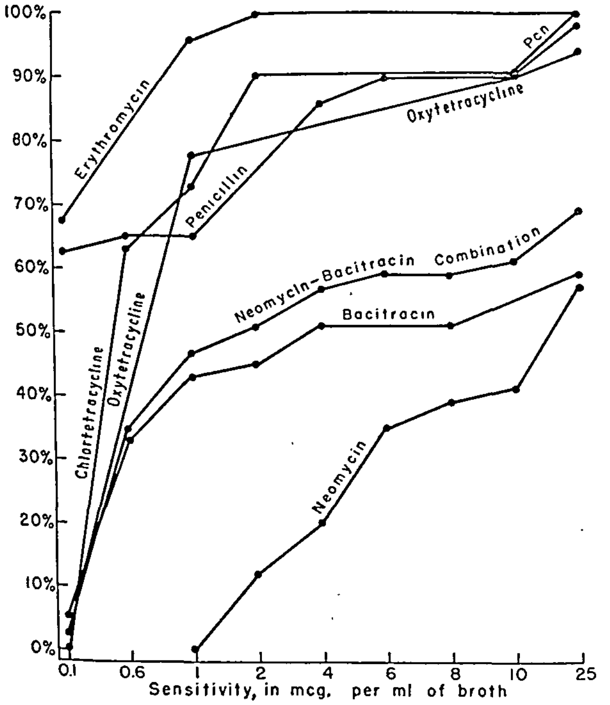

Fig. 1.—Results of in vitro sensitivity tests with various antibiotics of 60 strains of Micrococcus pyogenes var. aureus (hemolytic Staphylococcus aureus). All the strains were coagulase positive.

Bacterial cultures were done in almost all cases, and in many instances the cultures were repeated during and after the course of treatment. In vitro sensitivity tests to erythromycin, penicillin, chlortetracycline (aureomycin), oxytetracycline (Terramycin), neomycin, bacitracin, and the combination of equal parts of bacitracin and neomycin sulfate, with the standard multiple tube method, were done for 60 strains of M. pyogenes var. aureus (Staph. aureus) (fig. 1) and 49 strains of Strep. pyogenes (beta hemolytic streptococci) (fig. 2), hereafter referred to as hemolytic Staph. aureus and hemolytic streptococci. With this method the size of the inoculum is 1 by 10^6. All tests are read at the end of 24 hours. Tryptose phosphate broth was used for staphylococci, and horse meat infusion broth was used for streptococci.

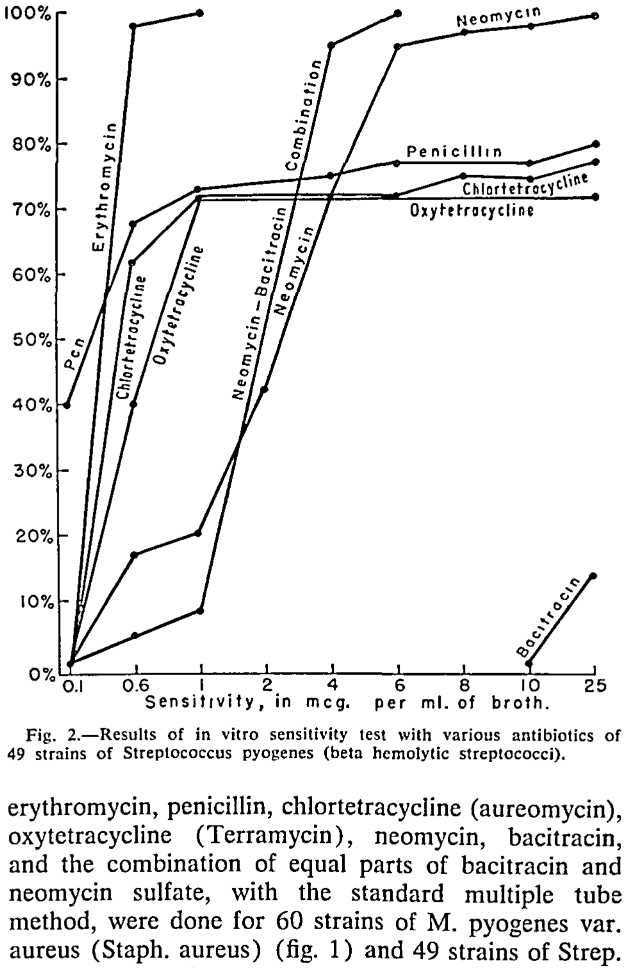

Fig. 2.—Results of in vitro sensitivity test with various antibiotics of 49 strains of Streptococcus pyogenes (beta hemolytic streptococci).

RESULTS

Our results with topical erythromycin therapy are summarized in tables 1 and 2. We did not attempt to evaluate the comparative efficacy of the various types of ointment bases, although in general we noted no significant difference. Furthermore, our experience with the combination of erythromycin and neomycin as compared with erythromycin alone was not sufficient to be of statistical significance. We did not note a superior therapeutic effect when the concentration of erythromycin was increased to 1% (10 mg. per gram of ointment base) rather than 0.5%.

Erythromycin ointment and the combination of erythromycin and neomycin sulfate ointment in all types of ointment bases studied were very effective in almost all of the 41 patients (fig. 3 and 4) with various types of primary cutaneous bacterial infections. We have not included exact data that pertain to the average number of days of treatment that were necessary to affect the clinical results, because to do so would involve the daily observation of each patient and that was not possible. However, in general, the patients with impetigo were cured within a period of from three to seven days. Those with ecthyma were cured within a period of from 6 to 14 days. The one patient with pustular folliculitis who did not improve significantly was uncooperative.

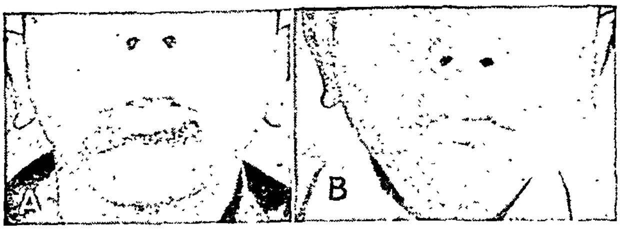

Fig. 3.—*A*, impetigo contagiosa before treatment with 0.5% erythromycin ointment applied three times daily for three days. *B*, after treatment.

As would be expected, the results in the treatment of the group of patients with various types of so-called secondary cutaneous bacterial infections, summarized in table 2, were more variable. It is necessary to emphasize that those patients whom we classified as "improved" had very satisfactory results in that the apparent bacterial infection factors was controlled completely insofar as this could be determined, but complete cure did not occur. Therefore, they were classified under the category of "improved" rather than "excellent."

It is obvious that numerous other predisposing and etiological factors must be considered in treatment of secondarily infected dermatitis of various types, otitis externa, perleche, nummular eczema, and ulcers. For example, one would not expect to effect a cure of atopic dermatitis by control of the secondary bacterial infection. We have the impression that local and systemic antibiotic therapy does not influence the course of kerion celsi significantly.

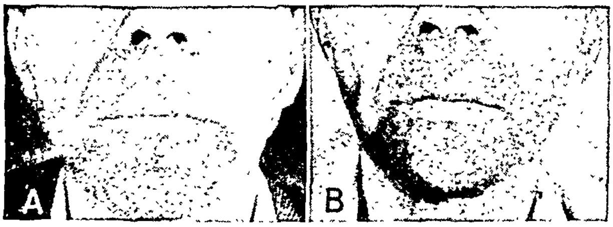

Fig. 4.—*A*, pustular folliculitis of the bearded region of three months' duration before treatment with 0.5% erythromycin ointment applied three times daily for 14 days. *B*, after treatment. Another patient with similar involvement did not have a satisfactory therapeutic result with erythromycin ointment.

It is well known that patients with nummular eczema do not tolerate greasy ointment vehicles, and it has been our experience that other antibiotic ointments are not particularly useful in the management of this condition. This must be kept in mind in interpreting the results with erythromycin ointment in this series of five patients.

It is difficult to evaluate the influence of any topical medicament in effecting the healing of removal sites. In some patients, especially those with removal sites on exposed surfaces, healing seems to proceed more promptly when no topical treatment is applied. If significant secondary bacterial infection occurs in a removal site incident to an electrocoagulation procedure, such as the treatment of an epithelioma, local antibiotic therapy may be very effective. In some cases erythromycin ointment seemed to be specific in its effect, but in other cases the application of an antibiotic in the form of a lotion effected more rapid healing of the removal site after the application of erythromycin ointment was discontinued.

* In these patients, bacterial infection seemed to be an apparent complicating factor; in some patients with impetiginized eczematous dermatitis and otitis externa, bacterial infection was the possible primary etiological factor, and in many patients with impetiginized dermatitis and removal sites, the bacterial infection had delayed healing significantly.

† See the tabulation in the text.

‡ Secondarily infected contact dermatitis, superficial fungus infection, and others.

The rather high percentage of results that were classified as excellent (22 of 30 patients) must be interpreted with the reservation that this indicates only that healing occurred following the use of the erythromycin ointment; this does not mean necessarily that the treatment was responsible for more rapid healing of the lesions.

REACTIONS TO TREATMENT

Three patients had distinct, clear-cut exacerbations of their skin lesions following the application of erythromycin ointment. In each instance, the cause was traced to the erythromycin rather than to the ointment base. In two of these patients the erythromycin ointment was reapplied after the reaction had subsided, and the same sequence of events occurred. Patch tests to erythromycin ointment were positive in only one of these three patients (only two patients were tested). In the following tabulation we have summarized the other reactions (in addition to those due to erythromycin shown in table 2) that were noted in this series of patients. Both groups of patients treated with a neomycin-erythromycin combination had previously had no reaction to erythromycin ointment.

Erythromycin	3
Combination of neomycin-erythromycin (one patient with removal site and one with otitis externa)	2
Questionable reactions to neomycin-erythromycin ointment (eczematous dermatitis)	3
Ointment base containing lanolin (two patients with eczematous dermatitis and one with atopic dermatitis)	3
Apparent delayed healing of removal sites	2

RESULTS OF BACTERIAL CULTURES

The organisms that were isolated on bacterial culture in this series of patients were (1) M. pyogenes var. aureus (hemolytic Staph. aureus) in 45% of cases, (2) the combination of hemolytic Staph. aureus and Streptococci (beta hemolytic streptococci) in 28% of cases, (3) hemolytic streptococci (pure culture) in 8% of cases, (4) Staph. albus in 9% of cases, and (5) Pseudomonas, Proteus, A. aerogenes, or other gram-negative bacilli in 10% of cases.

RESULTS OF IN VITRO SENSITIVITY TESTS

In vitro tests were done for 60 strains of M. pyogenes var. aureus (hemolytic Staph. aureus) and 49 strains of Strep. pyogenes (beta hemolytic Streptococcus). All of these strains were tested to erythromycin and five other antibiotics as well as the combination of equal parts of bacitracin and neomycin. Our results are summarized in figures 1 and 2, which are self-explanatory. In addition, a few strains of Pseudomonas, Proteus, and Esch. coli were tested with erythromycin, and in all cases the sensitivity level was more than 50 mcg. per milliliter.

Analysis of these results indicates that for staphylococci the order of in vitro effectiveness of these antibiotics was erythromycin, neomycin-bacitracin combination, neomycin, chlortetracycline, oxytetracycline, and bacitracin (penicillin is not considered in this list because it is not recommended for topical application). For hemolytic streptococci the order of effectiveness was erythromycin, chlortetracycline, oxytetracycline, neomycin-bacitracin combination, bacitracin, and neomycin. It is interesting to note that, in the sensitivity tests done with penicillin, chlortetracycline, and oxytetracycline, there was very little difference in the percentage of sensitive strains through the range of concentration from 0.6 mcg. to 25 mcg. per milliliter; this was in striking contrast to the results that were recorded for neomycin and the combination of neomycin and bacitracin in that an increase of concentration from 2 mcg. to 6 mcg. per milliliter resulted in a very marked increase in the percentage of sensitive strains. This same phenomenon was noted in the case of beta hemolytic streptococci. In other words, with chlortetracycline, penicillin, and oxytetracycline, a given percentage of these strains of both staphylococci and streptococci tended to be very sensitive to the antibiotic or relatively resistant.

COMMENT

It is almost impossible to define the sensitivity of a given organism to an antibiotic when it is applied topically. One would assume that it is possible to maintain a very high concentration of the antibiotic at the site of involvement in contrast to the relatively low blood level with systemic administration of an antibiotic. In practice, however, the clinical results do not seem to follow this pattern. In most cases, it has been our experience that adequate control of the bacterial infection factor following topical application of the antibiotic may be expected if the sensitivity of the organism is of the order of magnitude of from 0.1 to 10 mcg. per milliliter; the clinical response seems to be more rapid and more predictable if the sensitivity level is not more than from 4 to 6 mcg. per milliliter. In contrast, it is our impression that the clinical results to be expected when the sensitivity level is higher than 10 mcg. are unpredictable and in general not satisfactory.

In previous papers[6] we have summarized our own experience and opinions as well as those of other investigators[7] in regard to the relative effectiveness of the various antibiotics that are available for the topical and the systemic treatment of cutaneous bacterial infections. Of the available antibiotics that are suitable for topical use, we prefer the combination of neomycin sulfate and bacitracin, oxytetracycline, chlortetracycline, and neomycin sulfate; polymyxin B is the local treatment of choice only for cutaneous infection due to Pseudomonas organisms.

The clinical results that we have summarized in tables 1 and 2 indicate that erythromycin is another effective antibiotic for the local treatment of cutaneous bacterial infections due to hemolytic Staph. aureus and beta hemolytic streptococci. The antibiotic is not effective for the gram-negative organisms, which seem to be of etiological importance in some cases; the addition of neomycin sulfate to the ointment results in a preparation that does have a gram-negative antibacterial spectrum. It appears to be at least as effective for streptococci as chlortetracycline, oxytetracycline, and the combination neomycin-bacitracin preparations and as effective for staphylococcic infections as neomycin sulfate. In a few patients with chronic impetiginized eczematous dermatitis, it was more effective in that the condition was cured or marked improvement effected after treatment with other antibiotics (both local and systemic) had failed.

We have the impression that erythromycin is slightly more irritant for denuded and eczematized skin than neomycin, bacitracin, chlortetracycline, and oxytetracycline. We do not have evidence at this time, however, that the antibiotic has a higher sensitizing potential than the other antibiotics that are recommended for topical use. Additional experience must be accumulated before the semipermanent or final place of erythromycin in our therapeutic armamentarium for the local treatment of cutaneous bacterial infections is established.

---

Finally, if a sensitizing antibiotic such as penicillin is not considered, there is close correlation between the in vitro sensitivity tests and the clinical results. In this respect erythromycin shows great promise provided an increased percentage of irritant and/or sensitization reactions does not interfere with its therapeutic effect. However, the possibility of subsequent development of resistant strains of staphylococci and streptococci must be considered.

SUMMARY AND CONCLUSIONS

Our experience with the topical use of erythromycin in the treatment of cutaneous bacterial infections is reported; a total of 184 patients is included in this series. The majority of these patients were treated with a 0.5% ointment. A combination of neomycin-erythromycin ointment was used in some cases. It appears that erythromycin is a very effective topical therapeutic agent for staphylococcic and streptococcic primary cutaneous infections; the results in secondary bacterial infections were variable. Results of in vitro tests for 60 strains of hemolytic Staphylococcus aureus and 49 strains of beta hemolytic streptococci are reported; drugs used in this in vitro study included erythromycin, chlortetracycline (aureomycin), oxytetracycline (Terramycin), penicillin, neomycin, bacitracin, and a combination of equal parts of bacitracin and neomycin sulfate. Three patients had an apparent sensitivity or irritant reaction to erythromycin, and two additional patients had a similar reaction following application of the neomycin-erythromycin combination ointment. One of the ointment bases (lanolin) was not tolerated in three other patients. It is possible that erythromycin is not as well tolerated by denuded and eczematized skin as certain other antibiotics.

SEX AND AGE IN MYASTHENIA GRAVIS AS CRITICAL FACTORS IN INCIDENCE AND REMISSION

Robert S. Schwab, M.D.
and
Charlotte C. Leland, A.B., Boston

Since the communication on removal of the thymus as treatment for myasthenia gravis was presented by Blalock[1] in 1941, there have been a number of other reports on this procedure as a therapy in myasthenia gravis. Some of these have been enthusiastic as to the benefits achieved by removal of thymic tissue, particularly when it was not associated with tumor, in producing complete or partial remission in this disease. Geoffrey Keynes has reported the largest series of such operations, nearly 200. The first 100 of his patients were studied in considerable detail by Ross,[2] who reported that the operation benefited 86 patients. There was statistical evidence that the sooner the operation was done after the onset of the disease the more favorable the result. On the other hand, Eaton and Clagett[3] reported little statistical difference in remission rate between 70 patients treated by this operation and their control group of patients that had not been treated surgically.

Schwab and Passouant[4] reported on 50 patients thymectomy, in whom the remission findings were related with sex and age. The most favorable res were found in the young female group rather tha males. Eaton[5] reported a reevaluation of the result thymectomy in his series, and indicated that there new evidence that made him feel that the operation duced a greater percentage of remissions than in the trol series, but he was not quite satisfied with the statist analysis of this material. There still is, therefore, s question as to the precise value of thymectomy in m thenia gravis in spite of study of adequate number patients subjected to the procedure and compariso these results with a control series.

Since there was a difference in response to the op tion in females and males, we plotted the onset of the ease according to decades in the two sexes in a total gr of 367 patients on whom we had accurate informat about the date of onset (fig. 1). This showed a signific and surprising difference between males and fema The disease developed in 62% of the 202 females bef the age of 31. In contrast to this early beginning in females, in the 167 males the onset occurred bef the age of 30 in only 27%. For females the mode (21 onset age was 21 to 25 years, whereas for males the m (30%) onset age was 61 and over.

The significance of this sex difference in onset is once apparent in the various series of thymectomy ca reported in the literature, and in all of them there two or three times as many females as males. This wo be the obvious result of random selection of the surg cases, since the most favorable subject for a serious

eration such as thymectomy would be the younger patients. In our group of 78 patients, 53 were females and 25 were males.

In analyzing our data, we used controls that matched the thymectomy patients by sex, age of onset (within five years), severity of disease, and presence or absence of thymoma. These factors had all been found important in determining the good effects of thymectomy. The 78 controls were selected from a group of 250 myasthenia gravis patients. The influence of these variables was then compared. Patients in both groups were classified as to the presence of a remission as follows:

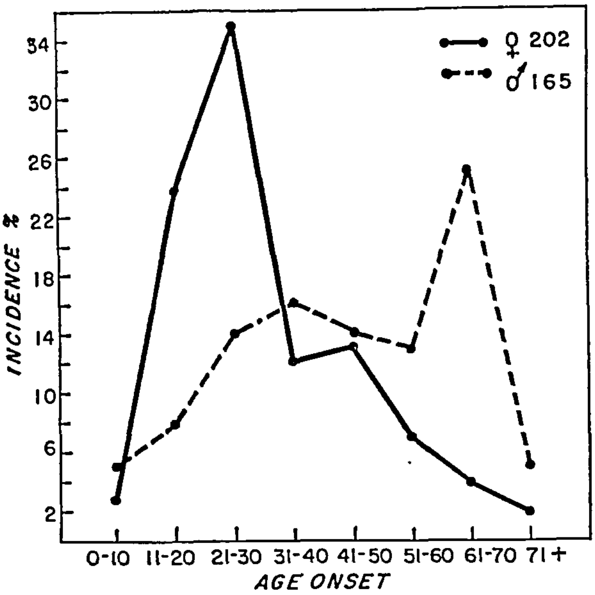

Fig. 1.—The distribution by decades of the onset of myasthenia in 367 patients.

A. This group had a complete remission. They no longer required any medication and had no symptoms.

B. This group was significantly and objectively improved, took less medicament, and had fewer symptoms. Medical referees would all agree as to the presence of improvement.

C. In this group were included patients with various degrees of slight to moderate improvement, which was subjective oftener than objective, difficult to evaluate quantitatively, and would not convince skeptical referees.

D. This group consisted of patients whose symptoms were unchanged or worse.

E. This group included the patients who died. The operative deaths and deaths from myasthenia were grouped together.

RESULTS

There was no significant mathematical difference in remission rates in relation to age or sex in the patients who had thymomas that were removed. In male patients subjected to thymectomy there was an A or B remission rate of 24% compared to a remission rate of 56% in males who did not have a thymectomy. Males subjected to thymectomy had the lowest remission rate and the highest mortality rate (table 1).

The A or B remission rate of females subjected to thymectomy was 63% contrasted with an AB remission rate of only 34% in those not subjected to surgery. This difference is statistically valid at the 1% level when tested by the Chi square formula. The mortality rate is correspondingly different for the two groups, the controls having nearly twice the mortality rate of the females subjected to thymectomy (28% vs. 15%). Figure 2 shows this in graphic form. In 44 females without thymomas, the A or B remission rate was 68%. These figures are conservative, as exclusion of thymoma cases raises the

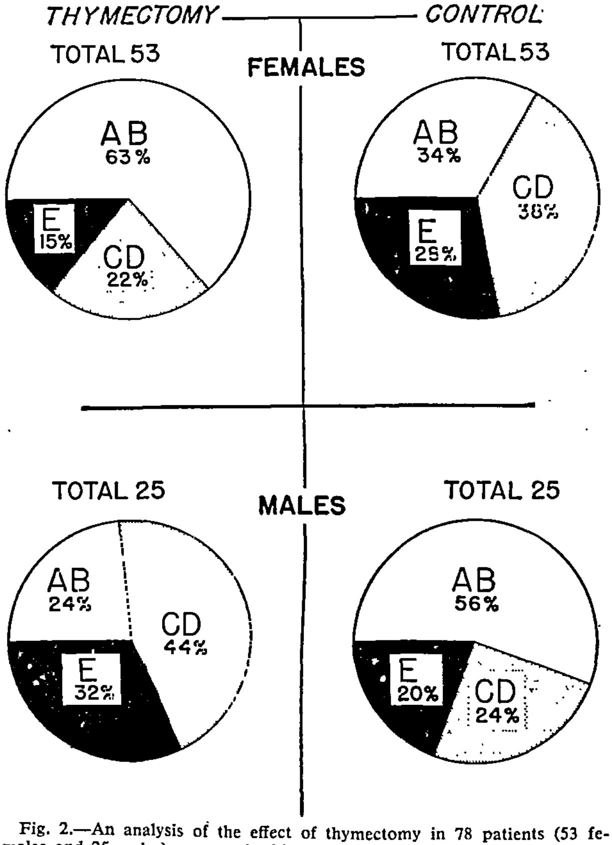

Fig. 2.—An analysis of the effect of thymectomy in 78 patients (53 females and 25 males) compared with a similar group of controls. Note the better remission rate and lower mortality in the females subjected to thymectomy as compared to the controls. The reverse was true of the males.

AB remission rate of the females subjected to thymectomy and lowers the mortality rate. We avoid comparison of the groups that did not have thymomas, as it is possible that some controls had thymomas that were not detected on chest roentgenograms.

It was suggested that we determine the remission rates at some specific time after thymectomy to see if they differ significantly from the end result figures. In 44 females without thymomas, for example, 59% could be classified in groups A or B within one year of the operation. There is no significant difference between the rates found within one year and those shown in table 1.

Table 2.—*Relation of AB Remission Rate to Total Known Duration of Myasthenia in Patients Subjected to Thymectomy and Controls*

0-3	12	7	58	21	8	38	8	2	25	7	3	42
4-7	25	17	68	19	3	16	5	1	20	5	3	60
8+	16	9	51	13	7	54	12	3	25	13	8	62

A study of the duration of illness from the onset to the time thymectomy was done showed that a duration of none to four years is apparently beneficial for females (not significant to 5% level) but not for males. These groups were analyzed as to age of onset to see whether more young patients were included in the short duration group, thus causing the increased benefit. This was not so, since the group of females with shorter duration was complicated by more thymomas and older patients. This agrees with the conclusion of Keynes that early intervention increases the remission rate. One should note that more of his patients were females in a ratio of 3: 1, and we believe that early intervention increases the remission rate only for the females. Table 2 illustrates this finding.

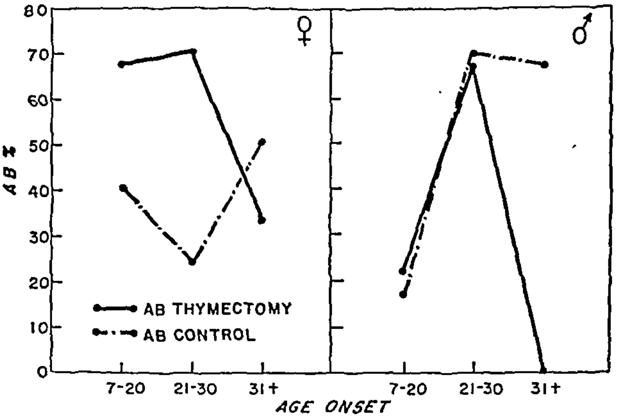

Fig. 3.—The rate of AB remissions in relation to age of onset in the two sexes, in patients subjected to thymectomy, and in control groups. Note that there is no significant difference between the second and third decades in the group subjected to thymectomy, but the remission rate is worse in the controls between the ages of 20 and 30. There is a sharp drop in the remission rate in females over 30 who have been subjected to thymectomy. Before the age of 30 there is no difference in the remission rate of males subjected to thymectomy and the controls, but there is a sharp decrease in the benefits of the operation in males over 30.

Female thymectomy patients who have had their disease over seven years had slightly less improvement than their controls. This figure suggests that a female having myasthenia gravis for that length of time would be better off without thymectomy. Male controls tended to improve with the passage of time. This natural tendency to improve was offset in the thymectomy cases.

The exclusion of thymoma cases raises the AB remission rates (except for males) and lowers the death rate. The thymoma patients of both sexes who did well had mild myasthenia. Male patients with or without thymomas who were subjected to thymectomy had the same low (24%) rate of AB remissions, although the mortality rate for all males (32%) is nearly double that of the group without thymomas (18%). Thymomas were present in 29% of males in whom the onset was before age 31 and in 36% of those over 30. The radical drop in AB remissions for males over 30 (statistically significant at the 1% level) is not due to the presence of thymomas, nor is there an increased proportion of severe cases in the older group.

Of the female thymectomy patients, only 5% of those under 31 and 78% of the older patients (a total of nine) had thymomas. The high proportion of thymomas in older females probably explains their poorer result. Thymectomy in patients with thymoma lowered the remission rate for females, did not alter it for males, and raised the death rate for both. Thymectomy is of uncertain value as a therapeutic measure in myasthenia gravis in all patients with demonstrable tumors such as thymomas and in all males.

The method of selection of patients for thymectomy depended partly on chance, economic reasons, and random persuasion in different periods by a number of different physicians, with a large number of variables. There has been, however, a trend toward selection of younger patients. In the period 1938-1945 in 44% of patients of both sexes combined the onset was after 30, whereas for 1946-1953 only 21% were of the older group. There has been a change in the proportion of males to females operated upon from 12 of 17 (71%) for the earlier period to 13 of 48 (21%) for the later period. Fewer patients with thymomas were selected in the later period, especially among males, where the proportion dropped from 42% to 23%. The decrease in patients with thymomas and in older patients and the increase in females are factors in the improvement of the results of thymectomies over the years.

The value of thymectomy in the females under 30 is compared to spontaneous improvement in the control group in figure 3. In the male group there is no difference in results in the surgical and control groups of patients under 30 years of age. In males over 30, the operation seems contraindicated, as shown in this figure.

COMMENT

In spite of the positive statistical correlation in these groups of cases, particularly in the group of females subjected to surgery as opposed to the controls, some investigators feel that the benefit of this chest operation in myasthenia patients may be due to the stress effect of the procedure. One can dismiss this, because myasthenia patients who have had major operations such as hysterectomy, or those who have suffered major fractures from accidents, emotional stresses, severe financial catastrophe, or death of loved ones, show a contrary effect under the stress of such trauma. Universally they show an increase in myasthenia symptoms and require more medication. They return to their previous condition only after a lapse of time. Of 30 patients who encountered such stressful situations, 28 showed a temporary increase in their disease.

Some clinicians are skeptical that there is any relation at all between myasthenia and the thymus gland. According to our figures, 17 (22%) of 78 patients subjected to thymectomy had thymomas. In Rowland's[6] series of 35 cases of death due to myasthenia, there was a 31% incidence of thymomas. The incidence of thymomas in ordinary postmortem examinations (in cases without myasthenia) is less than 1/10 of 1%. In our thymectomy cases, 60% of patients who did not have thymomas had abnormal thymic tissue in the sense that there was hyperplasia or presence of germinal center formations. The relationship seems indisputable. In view of the poor results of thymectomy in patients with thymomas and in male patients irregardless of pathology, it is likely that the causal agent is not the thymus itself but another endocrine disturbance that may cause both the thymic abnormalities and the myasthenia.

In our series of patients we feel that we have sufficient data to warrant the conclusion that the operation is indicated in younger females. In the 25 males who have been subjected to this procedure, our statistical consultants feel that a dogmatic conclusion of contraindication is not justified. They did not recommend, however, that additional males be operated on in order to increase the size of the group.

The seriousness of this disease is shown by the relatively high mortality rate. It is worth emphasizing that the females subjected to thymectomy have a decreased mortality rate (15%) as compared to their controls (28%). This includes the operative mortality, which was 7.5%. The operative mortality for males was 24%. An examination of the operative mortality rate for both sexes reveals that, prior to 1946, 5 of 17 patients died (29%). From 1946 through 1952, 5 out of 61 patients died (8%). Our data suggest that the young female patient has twice the chance of survival with thymectomy, and this better chance of survival is greatly increased owing to the experience of the surgical team, anesthesia personnel, and neurological indoctrination of the house staff.

SUMMARY AND CONCLUSIONS

The progress of 78 patients who have undergone thymectomy is analyzed and compared to a similar group who have not had surgery. The patients of all ages and both sexes who had thymomas demonstrable by either gross or microscopic examination derived no evident improvement in their myasthenia from the operation. Males received no evident benefit from the operation. Thymectomy appears to be contraindicated in males in whom the onset of the disease was after 30.

In females without thymomas, thymectomy appears definitely indicated. The incidence of unquestionable improvement in all 53 females who were subjected to thymectomy was 63% as opposed to 34% in the controls. The mortality rate, including operative deaths, was 15% for female thymectomy patients and 28% for their controls. More data indicate that the disease is twice as common in young females as in young males and twice as common in older males as in females.

SPECIAL ARTICLE

A HISTORICAL REVIEW OF MYASTHENIA GRAVIS FROM 1672 TO 1900

Henry R. Viets, M.D., Boston

Although myasthenia gravis was not described with any pretense of completeness as a clinical entity until the last quarter of the 19th century, a reference by Thomas Willis, an astute 17th century English clinician, indicates that Willis knew of the disease and recognized the chief symptom of asthenia of the voluntary muscles, with recovery after rest. The description of the weakness in his patient (1672),[1] first noticed by Guthrie (1903),[2] occurs in his book on the physiology and pathology of disease, with illustrative cases, "De anima brutorum," published in two separate editions the same year in Oxford and in London.

An English translation of "De anima brutorum" was made by S. Pordage in 1683 and published as "Two Discourses Concerning the Soul of Brutes" in "Dr. Willis's Practice of Physick" (London, 1684).[3] The significant part is as follows:

> There follows another kind of this Disease [i. e. the *Palsie*] depending upon the want and fewness of Spirits, in which, although motion be not deficient in any part or member wholly, yet it is not performed by any but weakly and depravedly only. For though the distemper'd are free from want of motion, they are not able however to move their members strongly, or to bear any weight; moreover, in every motive endeavour, they labour with a trembling of their limbs, which is only a defect of debility, and of a broken strength in the motive power. For when strength is wanting for the lifting up of any member firmly, and at one essay or endeavour, Nature flagging, acts with a more often repeated tryal or endeavour, and so the part being in motion is compelled as it were to shake and tremble . . . (p. 166).
>
> Not only *Scorbutical* persons, but also many others, hardly and long growing well from some *Chronical* Disease, are distemper'd with Members very much loosened from their due vigor and strength, and with a languishing of their Limbs; that though they are well in their stomach, and have a good and laudable Pulse and Urine, yet they are as if they were enervated, and cannot stand upright, and dare scarce enter upon local motions, or if they do, cannot perform them long: yea, some without any notable sickness, are for a long time fixed in their Bed, as if they were every day about to dye; whilst they lye undisturbed, talk with their Friends, and are

[1] Willis, T.: De anima brutorum, Oxford, Theatro Sheldoniano, 1672, pp. 404-406.

[2] Guthrie, L. G.: Myasthenia Gravis in the Seventeenth Century, Lancet 1:330, 1903.

[3] Willis, T.: Two Discourses Concerning the Soul of Brutes, translated by S. Pordage, London, 1683.

> cheerful, but they will not, nor dare not move or walk; yea they shun all motion, as a most horrid thing. Without doubt in these, although the Animal Spirits do after a manner actuate and irradiate the whole nervous Stock, yet their numbers are so small, and in so few heaps, that when as many spirits ought to be heaped together somewhere in it for motion, there is great danger left presently in the neighbouring parts, their continuity should be broken. Wherefore, when the spirits inhabiting the Brain, are conscious of the debility of others disposed in the Members, they themselves refuse local motions, for that it would be too difficult a task to impose on their companions; wherefore, the sick are scarce brought by any persuasion, to try whether they can go or not; Nevertheless, those labouring with a want of Spirits, who will exercise local motions, as well as they can, in the morning are able to walk firmly, to fling about their Arms hither and thither, or to take up any heavy thing; before noon the stock of the Spirits being spent, which had flowed into the Muscles, they are scarce able to move Hand or Foot. At this time I have under my charge a prudent and an honest Woman, who for many years hath been obnoxious to this sort of spurious *Palsie,* not only in her Members, but also in her tongue; she for some time can speak freely and readily enough, but after she has spoke long, or hastily, or eagerly, she is not able to speak a word, but becomes as mute as a Fish, nor can she recover the use of her voice under an hour or two (p. 167).

Thus Willis noted that his patients developed general, although partial, paralysis, that they were "not able however to move their members strongly, or to bear any weight," and that they "dare scarce enter upon local motions, or if they do, cannot perform them long." Some kept to their beds, neither wishing nor daring to be raised up or to walk about. In spite of the paralysis, his patients discoursed with their friends and were cheerful. Willis was particularly impressed by the strength shown by his patients in the morning. They were able to walk, move their arms, and lift a weight with strength; "before noon," however, "the stock of the Spirits being spent, which had flowed into the Muscles, they are scarce able to move Hand or Foot." The dysarthria of one patient, "a prudent and an honest Woman," was described in some detail by Willis. The disease had lasted for "many years" and was evident in the palsy not only of her limbs but also of her tongue. For some time she spoke "freely and readily enough," but after long, hasty, or laborious speaking she became "as mute as a Fish," only recovering her voice after an hour or two. There can be little doubt, therefore, that Willis, in the latter quarter of the 17th century, recognized the disease and described its principal symptoms.

Nearly 200 years were to pass, however, before myasthenia gravis was again referred to in the medical writings. The next recorded observation also was made by an English physician. Samuel Wilks (1877),[4] one of the physicians to Guy's Hospital, London, who, in describing some cases of bulbar paralysis and other neurological syndromes, described one patient with symptoms slightly suggestive of those seen in cases of myasthenia gravis. A girl could scarcely walk and had slight strabismus. No further change occurred in the first month; action and speech were slow and deliberate. At the end of this period she developed rapidly the additional symptoms of dysarthria and dysphagia. Unable to cough, she died of acute respiratory paralysis. The clinical record, as published, is so incomplete as to make the diagnosis difficult. Missing is the essential feature of myasthenia gravis, already noted by Willis, namely, recovery of muscular power after rest.

The report by Wilks, however, is important because the medulla oblongata was examined post mortem and no pathological signs of disease were found. "It appeared," wrote Wilks, "quite healthy to the naked eye, and the microscope discovered no manifest change in the tissue." This finding was strikingly different from the observations in cases of bulbar palsy, where cell degeneration was recognized by Wilks and his associates at Guy's as early as 1877.

Wilks' vague notation of 1877 passed almost unnoticed, as had the better account of Willis' patient, 200 years before. A more important presentation is that by Erb (1879),[5] who may be regarded as the first physician to write a reasonably full account of the syndrome. His paper was read May 18, 1878, although it was not printed until the next year. Two of his three patients were seen in Friedreich's clinic in Heidelberg, where Erb wa serving at the time as a physician.

Wilhelm Heinrich Erb, aged 38 in 1878, and long interested in muscular disorders, had first used the galvani and faradic currents for electrodiagnosis in 1868 and ha described the form of brachial palsy that goes by hi name in 1877. In 1878, his *Handbuch* in two volume was in the course of publication.

Erb's first patient with myasthenia gravis, a man c 55, was seen in 1868, 11 years prior to the publicatio of his case record. The patient's illness had develope over a period of *four months, the principal symptom* being bilateral ptosis, neck weakness, and dysphagia Some atrophy was noted in the neck muscles, and th response to faradism in the trapezii, masseters, an splenii was diminished. In six months, with galvanism decided improvement was noted. The patient, Georg Fuss, a day laborer, is worthy of notice, as he must have been one of the first patients examined and treated by electricity under Erb's care. When a remission occurred, it was natural for Erb *to attribute the improvement* to the galvanism. The patient was not followed beyond 1868.

A second patient from Friedreich's clinic was Magdalene Meisel, a peasant of 30 years of age, who was first seen on Oct. 17, 1870. Her early symptoms were diplopia and ptosis, dysphagia, and general weakness. During the next year there were frequent fluctuations in the severity of her disease. At one time she was nearly normal; later her speech became nasal, with marked general fatigue. After a period of recovery she died suddenly at night, in March, 1872. There was no postmortem examination. This is the first case in which there is a record of remissions and relapses. There is no mention of recovery after rest. Death occurred suddenly, as in Wilks' case.

Erb's third patient, August Thal, a merchant, aged 47, was first seen on July 11, 1871. For a year the patient had noticed weakness of his neck muscles. Later there was general weakness and he could not hold his head up. Bilateral ptosis was next observed, then weakness of the *facial muscles. No improvement was noted* after galvanism; the patient was followed only a month or two.

[4] Wilks, S.: On Cerebritis, Hysteria, and Bulbar Paralysis, as Illustrative of Arrest of Function of the Cerebrospinal Centres, Guy's Hosp. Rep. **22**:7-55, 1877.

[5] Erb, W.: Zur Casuistik der bulbären Lähmungen. (3) Ueber einen neuen, wahrscheinlich bulbären Symptomencomplex, Arch. Psychiat. **9**: 336-350, 1879.

All three cases described by Erb appear, 74 years later, to be examples of myasthenia gravis. The case of Magdalene Meisel is the most characteristic, and the progress of her disease to death is a story often repeated in the literature in subsequent years. The other reports, while not so definite and lacking the length of observation needed to make an accurate diagnosis, nevertheless describe cases clearly enough that they may be classified as cases of types of myasthenia gravis.

Erb's paper is, therefore, incomplete. It is of value, however, for Erb first brought out clearly some of the chief symptoms of myasthenia gravis, particularly the distribution of the paralysis in the muscles supplied by the bulbar nuclei, the progress by remission and relapse, the sudden death, and the frequency of ptosis as the leading sign of the disease. He mentions other symptoms, however, not commonly found, such as hyperacusis in the first and second case, and headache, vertigo, and sharp pains in some of the others. In spite of the inadequacy of his descriptions, from the present point of view, it must be realized that these three patients were taken from a large number of patients with bulbar paralysis, certainly an ill-defined group in 1879, and considered to have a new symptom complex. The syndrome was not, however, given a definite name. With only brief histories and periods of observation and without postmortem studies, Erb saw something unusual about these three patients and had the genius to visualize a previously undescribed, as far as he was concerned, disease. Erb might rightly be considered the first physician to bring myasthenia gravis to the attention of the medical world. He published his paper, moreover, in a standard medical journal, which was, although only nine years old, devoted exclusively to psychiatry and neurology, where it was most likely to be seen and evaluated by others competent to judge its worth.

The first to do so was Eisenlohr (1887),[6] a physician from Hamburg, who added another case report eight years later. The patient, a girl, aged 18, was seen in the summer of 1886. His account is chiefly notable for his observation of variations in the patient's symptoms in the course of a single day, a point not previously mentioned by others. Chief emphasis was placed by Eisenlohr on the external ophthalmoplegia, which was accompanied by attacks of migraine, dating back to early childhood. The terminal manifestations of diaphragmatic paralysis, with no abnormalities found on postmortem examination, however, lead me to believe that a diagnosis of myasthenia gravis was justified. Death, in females at about this age, is one of the most characteristic features of the disease, as will be illustrated frequently in later reports.

Oppenheim (1887), an assistant in Westphal's clinic at the Charité in Berlin, reported still another case. While Oppenheim was the first to notice Wilks' case of 10 years before and quotes it in full, he does not mention for some reason the three cases described by Erb in 1879. Oppenheim was particularly interested in the differential diagnosis between hysteria and myasthenia gravis and noted that Wilks' house physician was inclined at first toward a diagnosis of hysteria in the London case. His patient, Pauline Jahnke, a 29-year-old maidservant, was observed for over a year. There was marked variation in the severity of her symptoms; she died in a dyspneic attack. The postmortem examination revealed no abnormalities.

The case reported by Shaw (1890),[7] although a careful study of the pons and medulla post mortem failed to show any signs of structural disease, is important historically because of the observation, first made by Willis, that the patient's "symptoms were but slight in the morning, but became more evident as the day advanced." This fact had long been unnoticed until revived by Shaw. The patient, a 37-year-old baker, had symptoms for only six months before death. He showed the usual dysarthria, dysphagia, diplopia, and difficulty in mastication and expectoration. Shaw notes particularly the "copious secretion of frothy mucus" and gives a vivid account of the terminal respiratory paralysis and failure of artificial respiration, reported for the first time in the treatment of myasthenia gravis.

The striking changes in the eye muscles were naturally one of the first symptoms to attract attention. Bernhardt (1890) made particular note of this. His patient, a joiner, aged 44, first noticed diplopia in August, 1866. By November there was double ptosis and difficulty in mastication. In February, 1877, he was well, and his remission lasted until 1890, the longest recorded up to that time. Six months later, however, neck weakness, dysarthria, and general weakness developed, with dyspnea, only to be followed by a brief period of improvement. The patient died suddenly before the year was out; there was no autopsy. The reporting of a 3 year remission, coming on 10 years after the onset of the disease, was the chief addition by Bernhardt to our knowledge.

An American student, Hermann Hoppe (1892),[8] working in Oppenheim's clinic and laboratory in Berlin, reported a fully studied case in 1892, with no abnormal findings at postmortem examination. Hoppe's patient, a blacksmith, aged 40, was observed for over a year with symptoms of bilateral ptosis, dysarthria, and dysphagia. There was weakness of both facial muscles, as well as those of mastication, the abductors and adductors of the vocal cords, and the extremities. Electrical reactions were normal, and there was no atrophy. The postmortem examination of the nervous system was more complete than in any previously described case; no lesions were found. Hoppe compared his case in detail with those of Wilks, Oppenheim, and Eisenlohr. His report contains the most comprehensive review of the disease up to 1892.

In a report on three cases of bulbar paralysis by Remak (1892), the second case is highly suggestive of myasthenia gravis, in spite of the fact that the girl was only 12 years of age. She suffered from influenza in February, 1890, and noticed facial weakness and dysarthria the following July. By September, she had dysphagia, nasal speech, and weakness of the tongue and lips. Some improvement followed, but she had difficulty in expectoration and attacks of dyspnea. Weakness of the arm was next noted. Death occurred from respiratory

paralysis in November. There was no postmortem examination. The chief interest in the case historically lies in the age of the patient, one of the youngest on record.

Dreschfeld (1893), of Manchester, England, described another case in great detail under the title of "Polioencephalomyelitis Without Any Anatomical Lesions." His report is the first emphasizing the long history of symptoms, characteristic of myasthenia gravis. Double ptosis at the age of 21 was followed, after six months, by a remission lasting five years. Five years later the patient suffered a second attack, which continued intermittently for 10 years. She died at the age of 36 of respiratory paralysis. An extensive postmortem examination failed to disclose any lesions in the nervous system. For 10 years, between the second and third attack, she was able to work as a dressmaker and in the bakehouse of an almshouse. She ate slowly, with frequent rest periods, supporting her jaw with her hand. There was also weakness of her shoulders. During the long period only the eye symptoms improved. In spite of the title of his report, Dreschfeld compares his case with those reported by Hoppe, Wilks, Eisenlohr, and others.

With a score or more cases reported by 1893, some with negative examinations of the pons and medulla, Goldflam (1893),[9] added greatly to our knowledge of the disease and his name is rightfully coupled with that of Erb in the eponym the Erb-Goldflam symptom complex. He not only added three important case reports to the literature but also analyzed the symptoms in a manner superior to any writer before him. He noted the early bulbar symptoms, which often come on in a few weeks or months after the onset, the facial weakness, and the involvement of the trunk and neck muscles. The rapid exhaustion of all muscles was particularly emphasized. He was not unmindful of remissions and exacerbations, particularly those occurring in a period of 24 hours or less. All three of his patients were worse in the evening. To differentiate his cases from bulbar paralysis as described by Duchenne, Goldflam pointed out the lack of atrophy of the muscles affected, the absence of fibrillation, the normal electrical responses, the presence of sphincter control, the normal or lively reflexes with reflex exhaustion after continuous stimulation, and the normal palatal reflex. Some of these points had been noted before, but Goldflam synthesized the whole picture and made clear the differential diagnosis between myasthenia gravis and bulbar palsy. Goldflam, moreover, stressed the attacks of dyspnea and, although none of his patients died under his observation, he nearly had a fatality as the result of the examination of the larynx of one of them. Finally, he noted the weakness of the muscles supplied by the fifth cranial nerve in myasthenia gravis, a muscle group rarely, if ever, paralysed in bulbar palsy. Entirely familiar with the previous literature, Goldflam realized that his three cases were examples of a benign type of the disease.

Goldflam, in his summary, established the following points: The disease often occurs in early life. The sexes are about equally affected. Myasthenia gravis is primarily a disease of the motor system, with only occasional pains or paresthesias; chewing, swallowing and eye movements are most affected at first, followed by involvement of the trunk and extremities. The disease rarely has its onset in the arms or legs. The muscular involvement is usually symmetrical. The muscles supplied by the facial nerve are always involved, mostly the middle and lower branches; the muscles of mastication and those of the neck are next commonly affected. Stimulation results in rapid weakness. Most patients are worse in the afternoon. Twenty or 30 movements often bring the muscle response to zero. Daily remissions and relapses occur, but remissions may last as long as four years. The knee jerk may be exhausted by stimulation. Death may occur very suddenly. All of Goldflam's observations are valid today; in fact, little has been added to the clinical description of the disease since his time. His paper in many ways is the most important ever written in the history of the disease.

After Goldflam's paper, other cases were soon reported. Suckling (1893) observed two nonfatal cases in young women; Wernicke (1893) described the now somewhat recognized syndrome in a young woman who died suddenly of asphyxia. Examination of the nervous system post mortem revealed no abnormalities except some vascular dilatation and recent hemorrhages. A similar case, with death from sudden choking, was reported by Mayer (1894). Wernicke's observation on th thymus was not to be made until 10 years later.

Jolly (1895),[10] who first gave the name myastheni gravis pseudoparalytica to the disease, published report of two cases. A preliminary report of the first case wa given in 1891, but both cases were described in detai in 1895. The first patient was a boy of 15, with many symptoms of eight months' duration. When his muscles were stimulated repeatedly with faradism, a reaction o asthenia was promptly demonstrated. This, the "myasthenic reaction," was recorded in tracings. The patient died suddenly while eating, with a piece of food sticking in his throat. No abnormal changes were found in either the nervous system or in the muscles.

Jolly's second patient was also a boy, aged 14, who had had symptoms for over a year, beginning with ptosis. Subsequently, there was great weakness in his arms, legs, neck, and muscles of mastication. The speech became so indistinct that Jolly was reminded of general paralysis. All voluntary muscles were readily exhausted and Jolly noticed that exhaustion of one group of muscles was seen to produce asthenia in others. The child was always better after rest, particularly in the morning. While eating he had to stop frequently because of weakness in chewing; speech became indistinct if he read aloud, but he did not become "mute as a fish"; dysphagia was not present.

Jolly thus was the first to analyse the reaction of muscles in myasthenia gravis to electrical stimulation and to name the disease. He also suggested physostigmine as a form of treatment, but he does not seem to have followed out this important point and it was left to Walker 40 years later to demonstrate the therapeutic value of this drug.

Pineles (1895) added reports of four more cases, one with rapid onset in a man of 25. Two of his patients died suddenly of dyspnea, justifying, as had many others, the correctness of the term "gravis" in the designation of the disease given it by Jolly. Pineles seems to have been the first to refer to myasthenia gravis as the "Erb-Goldflam bulbar symptom complex."

[10] Jolly, F.: Ueber Myasthenia Gravis Pseudoparalytica, Berl. klin. Wchnschr. 32: 1-7, 1895.

Up to 1895, all the reports of cases had come from England, Germany or Austria, the majority stimulated by the pioneer work of Erb, Goldflam, and Jolly. Soon case reports began to come in from France, from Italy, and from America. The first from France came from Charcot's old clinic in Paris, where Marinesco found some recent hemorrhage beside the aqueduct of Sylvius and in the vagal nuclei post mortem in a case formerly observed by Charcot and Brissaud. The brief report was issued two years after Charcot's death under the name of both authors, Charcot and Marinesco (1895). No mention was made of any previous descriptions; the disease was not named.

Murri (1896) [11] reported the first case of Italy under the name of Erb's disease. He used the electrical reactions described a year before by Jolly, and pointed out, in addition to Jolly's observations, that, even when complete *exhaustion* was produced by an electrical current, the muscles could readily contract voluntarily. He also showed the reverse, namely, that muscles exhausted voluntarily would still react to the electrical current. His paper was illustrated by a series of myograms, exquisitely reproduced and far superior to those found in Jolly's paper in 1895. He was much influenced by Mosso, the Italian physiologist, who had long been interested in myograms. Murri also noted the daily variation in his patient's symptoms.

Another case was added to the literature by Strümpell (1896), who observed a girl, 21 years of age, from Dec. 30, 1893, until her death on March 27, 1894. Particular attention was called to the rapid exhaustion of the muscles and to the fact that the patient was worse during her menstrual period, the first indication in the literature that the disease might be affected by glandular activity. For the last three months of her life, the patient had almost daily attacks of dyspnea, with marked salivation. Death occurred from respiratory paralysis. Postmortem examination, particularly of the medullary nuclei, revealed no abnormalities.

Silbermark (1896) described a cook seen in Nothnagel's Klinik. The patient had noticed, while rolling dough, that the third and fourth fingers were weak and could not be normally extended. Later bulbar symptoms developed, with variations in intensity and duration. He always felt better in dry, warm weather. There were notable remissions.

The symptoms in the patient seen by Devic and Roux (1896) were chiefly neck weakness and ptosis, without other bulbar involvement. They report an excellent remission, followed by a mild relapse. At the same time, Fajersztajn (1896) was observing a man of 23 in Lemberg, who was so sick that he could not sit up in bed and even lifting a spoon to his mouth soon tired him. After six months in bed, improvement followed, but there were transient relapses.

The first paper from America, although not the first report of an American—for Hoppe had already written his paper at Oppenheim's Berlin clinic—is that of Collins (1897),[12] given as a clinical lecture in 1896. Collins reviewed the literature and presented a patient, aged 27, whose first symptom developed during pregnancy.

Kalischer (1897) also reported a case in a man of 50 in whom ptosis developed after an attack of influenza. Dysphagia, dysarthria, and general weakness were later noted, with a positive Jolly test. Kalischer thought there was an affection of the motor nuclei and used the term poliencephalomyelitis. He stressed the possibility of sudden respiratory paralysis after a remission.

Two cases were excellently described by Kojewnikoff (1897) of Moscow. The first, a man of 54, had marked weakness in chewing and swallowing, and tube feeding was resorted to. The patient died suddenly of respiratory paralysis. His second case is of more importance because of the use of the ergograph to test muscular weakness. A girl of 17 first noticed symptoms of a bulbar type at the onset of menstruation. The disease progressed by remission and relapse. During a relapse on one occasion she became dyspneic during sleep in an attack that lasted three hours, followed by recovery. The patient was tested for muscular weakness by the Jolly method and also by the use of the Mosso ergograph. Pulling a weight of 400 gm. with the third finger, once a second, caused rapid myasthenia.

Karplus (1897) separated from the general group of asthenic paralyses those with ophthalmoplegia as the first and most persistent symptom and called them asthenic ophthalmoplegia. In his patient, aged 24, other symptoms did not develop until after nearly 20 episodes of intermittent ptosis and diplopia, when she had general weakness and difficulty in chewing.

The first case in which a postmortem examination was done in America was that reported by Berkley (1897) [13] from Johns Hopkins Hospital. The patient had symptoms for seven years, dying suddenly. No changes were found in any of the motor cells. The case, while atypical, had many of the classical features of myasthenia gravis.

Widal and Marinesco (1897) observed a patient, aged 31, with acute bulbar paralysis. The onset was rapid, and, although there were some variations in the symptoms in the two weeks that the patient lived, the ptosis, diplopia, dysarthria, dysphagia, and general weakness never cleared up entirely. The symptoms were all worse in the afternoon and evening. Chromatolysis of the motor cranial nuclei and of some of the anterior horn cells was found on postmortem examination. The rapid onset, with death in two weeks, plus the changes found at autopsy, make the diagnosis uncertain. Similar cell changes are seen oftener in cases of acute ascending paralysis (Landry's syndrome).

Cohn's patient (1897),[14] a girl of 16, who died after a few months of illness, had a rapid, nonremitting type of myasthenia gravis. At autopsy hemorrhages into the brain stem of a petechial type were demonstrated. It was Toby Cohn who fixed the name of myasthenia gravis given to the syndrome by Jolly.

Schlesinger (1897) reviewed all types of bulbar paralysis seen at the University clinic in Vienna and found only one case of a doubtful nature. Brissaud and Lantzenberg (1897) gave a full review of the literature on myasthenia gravis and reported one questionable case. Eulenburg (1898) observed a patient for three years with intermittent ophthalmoplegia, and Wheaton (1898) reported a fatal case, without autopsy, from America.

Of more importance was the case reported by Mailhouse (1898),[15] for his patient was a boy, aged 2 years and 9 months, the youngest patient observed and reported on up to that time. The child, who had been healthy previously, died suddenly after a month's illness. There was no autopsy, but the clinical description of myasthenia was unmistakable. In Karplus's case symptoms had supposedly begun at the age of 5, but Mailhouse actually observed the disease before the age of 3. The brief duration before death was also a feature of Wheaton's case.

The subject was again reviewed, this time in Frankfurt, by Laquer (1898), with abstracts of previous cases and with the addition of a case of his own. He noted that the symptoms in his patient became intensified after an attack of bronchitis; the man, aged 49, tended to fall asleep after the midday meal and, as the disease progressed, considerable atrophy developed in the arm and leg muscles. Some muscles were also tender to pressure. The myasthenic reaction was present. As the patient had long suffered from gout, the atrophy and tenderness may have been due to neuritis or myositis and not the result of the myasthenia.

Saenger (1898) noted an improvement in his patient when she became pregnant, but details are lacking in his brief report. Montesano (1898) suggested an infectious element as the causative factor, and Kostezkaso (1898) noted weekly variations in the progress of the disease.

Campbell (1899) demonstrated a case before the Clinical Society of London, Feb. 24, 1899, and Seiffer (1899) another before the Berlin Society of Psychiatry and Neurology on Nov. 13 in the same year. At the latter meeting, the syndrome was discussed by Oppenheim, Bernhardt, Jolly, Kalischer, Remak, Mendel, and Toby Cohn. The name myasthenia pseudoparalytica (Jolly) was generally accepted, as had been suggested by Cohn two years before.

In America, two cases were reported at the 25th annual meeting of the American Neurological Association in 1899. Sinkler (1899)[16] was the first to show the facial appearance of a patient, a woman of 37, by photographs. Ptosis had existed for seven years, but dysphagia and general weakness occurred only after the birth of her sixth child, five months before she was seen by Sinkler. He did not give a clear picture of the patient's condition during the last pregnancy, but the chief symptoms appeared soon after it. Punton (1899), reporting at the same meeting, had observed a woman of 25 with typical symptoms. He was impressed by the "putty-like blankness" of her facial expression.

In discussion, Collins pointed out that his patient reported on in 1897, was always worse at the menstrua period. His patient also had an acute psychosis of the confusional type.

The year 1900 witnessed a great outpouring of literature on the subject. Cases were reported from many places in Europe and from America. The disease had become widely recognized. In Germany, Feinberg (1900 observed a man of 44, with an unusual onset of intestinal obstruction, occipital pain, and parasthesias. The later symptoms were more typical, and recovery took place in about six weeks. The patient remained well for the next year. Feinberg stressed the onset with "autointoxication." Giese and Schultze (1900) contributed a careful study to Erb's *Festschrift* of a married woman of 24 who had a tendency toward remission and relapse of single symptoms, but never of all symptoms at the same time. She was worse with the onset of menstruation. After a partial recovery, she suffered a psychic shock in the death of her child and immediately had severe dyspnea and other bulbar signs, with rapid relapse and death in two days. On examination, the brain was found to be normal. The authors felt that the disease should be named after Erb. Oppenheim (1900) described a case that was formerly considered as an example of hyperthyroidism or hysteria but later was recognized as a case of myasthenia gravis. The postmortem examination failed to show any changes in the brain cells. After reviewing 19 cases in the literature, all without cerebral lesions, Oppenheim felt that the disease was probably without anatomical basis but that congenital malformation of the brain might play a part in the etiology of myasthenia gravis. In his case he found some minor congenital abnormalities. Cohn (1900) added another case.

In Belgium, two cases were described by DeBuck (1900) and by DeBuck and Broeckaert (1900). In the first case, DeBuck found some atrophy, similar to that found by Laquer, and this caused him to be disturbed about the diagnosis. The other symptoms were characteristic and a diagnosis of myasthenia was finally accepted. The second case, reported by DeBuck and Broeckaert, was more typical of those described by Erb. The Jolly myasthenic reaction was absent, but the authors felt that this was not a constant sign, as had Oppenheim. They found 90 cases in the literature and considered their case the 91st.

In addition to the fine summary by DeBuck, an even more complete review was given by Guastoni and Lombi (1900) of Rome. They observed a patient over a period of nearly three years. He had a scaly, painful dermatitis in addition to many bulbar symptoms. The Jolly reaction was positive. After a number of months, recovery was complete. The authors gave a full discussion of Erb's disease, with a listing of cases previously reported.

In England, single cases were reported by Hall (1900), Guthrie (1900), and Batten and Fletcher (1900). Hall's patient was a woman who was much worse during her menstrual period and in the course of her illness had extreme mental depression. After a partial remission, she died suddenly after eating. The brain sections appeared normal. Guthrie's patient, a woman, aged 23, showed considerable variability in her symptomatology; she could eat breakfast well, but other meals were taken with difficulty. As in the original case of Willis, after she read a few lines aloud, her speech became unintelligible. The case was similar to Campbell's that was presented before the same society in 1899. Batten and Fletcher also observed the disease in a woman, aged 22, who lived only a few months. Death came after eating, in spite of artificial respiration and tracheotomy; the brain sections showed only slight abnormal signs in the cranial nerve nuclei.

---

[15] Mailhouse, M.: A Case of Myasthenia Pseudoparalytica Gravis (Jolly) or Asthenic Bulbar Paralysis (Strümpell), Boston M. & S. J. **138**: 439-441, 1898.

[16] Sinkler, W.: Asthenic Bulbar Paralysis, J. Nerv. & Ment. Dis. **26**: 536-544, 1899.

Buzzard (1900) reported on one case in a man, aged 40, who had symptoms for seven years. With rest, his symptoms almost entirely disappeared. His second case, in a woman, aged 24, was also not severe. The Jolly myasthenic reaction was present in each patient.

Campbell and Bramwell (1900) [17] reviewed the entire literature up to 1900, abstracted each case, and compiled a table giving the major symptoms and signs. Although they made a good many minor errors in tabulation, the paper was important, for it served to fix the main concept of the disease in the minds of the men in the British and American medical profession.

During 1900, two more cases were reported from America, one by Brown (1900) and another by Paul (1900).[18] Brown's patient, a woman, aged 29, was ill about 16 months; she lost 15 lb. (7.3 kg.) in weight and was greatly reduced in strength. She experienced a good spontaneous remission. Inability to do her hair was one of her chief symptoms. In the discussion of Brown's paper, four more cases were noted briefly by the physicians. Paul's patient, a 23-year-old woman who had been married for three years, had many typical features of the disease. This was the first case reported from the Massachusetts General Hospital. Following is an account of the symptoms based on the original clinical history:

Eight months before presenting herself at the hospital and 18 months after her confinement, while taking the part of a Japanese girl in private theatricals, she stooped low, in a line with a number of other performers; at a given cue all the line were to resume the standing attitude, but the patient could not rise and asked for help. She was ridiculed a bit and then assisted to stand. In the final performance she received assistance from her comrades on either side and suffered no further disability. Ascending stairs became difficult; in boarding a car she could not lift her feet without assistance. If merely helped in the usual way by taking of her hand or arm, she would be pulled forward and fall on her face. This loss of muscular power was of brief duration. Crossing the knees at times required assistance. She could usually walk on a level, but stepping up was frequently difficult. In spite of her myasthenic symptoms, she attended to her housekeeping and cared for her baby.

Transient weakness in the arms next appeared; at times they would drop like lead without sensory disturbance; her husband had to support them when she arranged her hair; to insert a hat pin she rested the elbows on the mantel. In playing the piano both hands tired easily. She would sometimes have to drag the baby to her lap rather than lift him clear. Once when she was attempting to take him from his crib it was impossible to straighten up until assisted. She refrained from handling objects. There was difficulty at times in buttoning, and ability to do millinery and embroidery was lessened. The attacks of weakness became more frequent. These symptoms were of short duration and came on usually after severe use of those muscles in which weakness or complete loss of power developed. She not infrequently fell backwards on stairs, and on one occasion when near the top her legs gave way and she fell with the baby in her arms, sliding down several steps without injury. Transient diplopia occurred in the course of the disease, and it was noticed at times that when she looked up the head was thrown back, indicating ptosis. The muscles of mastication escaped. There was lack of expression in the face, and the laugh seemed incomplete. The voice at times was nasal and somewhat indistinct, though not lowered. Words were correctly chosen, and speech was never really lost. One day the words ran together and the lips seemed powerless, but holding of the upper lip with the fingers obviated her difficulty. Swallowing was sometimes awkward, and in the later stages this difficulty became serious. The neck muscles sometimes suddenly gave way so that the head required support.

The symptoms became more frequent, and involved on several occasions very nearly all of the voluntary muscular system. One evening six months before death, after climbing the stairs safely, she fell to the floor unable to move or speak, but finally succeeded in attracting attention by tapping the floor with her heel. Later, in attempting one day to step up on the piazza, she fell in a heap and had to be carried bodily into the house. In a third instance, five weeks before death, she fell helpless at the top of the stairs. After a few moments she regained control of her muscles in each instance; some drowsiness followed the last attack, but no unconsciousness.

The most serious symptom to develop was choking, the first attack occurring about six months before death. At the commencement of a meal, the first attempt to swallow water caused strangulation; she became cyanosed and unconscious, but revived at the end of about 30 minutes. A month later, after she took two swallows of water without trouble, the third choked her. Cyanosis and unconsciousness followed, and Dr. Campbell, who was present, seriously considered tracheotomy. Such attacks and the accompanying apprehension impaired nutrition materially, but there was no local atrophy. Her mind remained clear. Palpitation and dyspnea occurred, but were not prominent symptoms.

There was no numbness or prickling. Appetite and digestion were good. The disposition was unaltered; the catamenia reappeared after confinement and did not modify the symptoms. The sphincters were unaffected; there was no spasmodic movement, stiffness, or tenderness. Emotional excitement aggravated the disturbance.

During the last few months of life the attacks of weakness became more frequent and profound, yet, when seen in the intervals, she gave no impression of serious illness. The bulbar symptoms became more pronounced and at one time rectal feeding was practiced; but the ability to swallow food and liquids returned while she was at the Boston City Hospital, some months before death. Toward the end she was sometimes unable to roll over or to sit up in bed, showing involvement of trunk muscles.

[18] Paul, W. E.: Case of Myasthenia Gravis Pseudoparalytica, Boston M. & S. J. 143: 632-634, 1900.

The ocular symptoms also increased, but there were remissions with apparent normal muscular balance. Exposure to cold did not aggravate the condition, as a rule; but once, on leaving the car after a journey, she became helpless on encountering the chill of a March air. Three days before death she was able to try on a dress, and two days before death she sat in a chair and swallowed without trouble. At this time she complained of palpitation and of a sharp pain in the right iliac region. The lungs filled up but became clear again after several hours; there was temporary inability to spit out or swallow the secretions. Death occurred 18 months after the first symptoms.

SUMMARY AND CONCLUSIONS

From 1672 to 1900 the concept of a disease, myasthenia gravis, was formed in the minds of a score or more of medical observers. Willis, the first of a distinguished line, grasped the essential clinical signs and delineated their identity in 1672. His description died aborning until uncovered by Guthrie in 1903, although it may have lingered smoldering in the minds of physicians in the 18th and 19th centuries, even to the point of influencing practice by a vague recognition of a specific disease. Nearly 200 years after Willis wrote his discerning note, another English physician, Wilks, in 1877 gave a brief account of a girl with symptoms suggestive of myasthenia. Although the history of his patient's illness is not entirely characteristic, difficulty in swallowing, talking, and breathing developed rapidly, and death occurred suddenly. At postmortem examination no microscopic changes were found in the medulla, strikingly in contrast to what was already common knowledge of the pathology of bulbar paralysis of the degenerative type. Wilks thus contributed the initial description of the failure to find pathological destruction of nerve tissue in the appropriate area of the central nervous system. Wilks' account, as had that of Willis', passed almost unnoticed. Two years later however, Erb in Germany wrote a reasonably full account of the syndrome based on the observation of three patients, one of whom died suddenly. An even more complete single case history was contributed by Eisenlohr in 1887, and subsequently within a few years many other reports were at hand, including an unusually detailed one by Hermann Hoppe, an American student working in Oppenheim's clinic in Berlin in 1892. Goldflam (1893) added greatly to the growing concept of the disease, and his name is rightfully linked with that of Erb in the eponym, the Erb-Goldflam symptom complex. Jolly (1895) was the first to use the name myasthenia gravis and he added the term pseudoparalytica because of the lack of structural changes found post mortem. This name was generally accepted at a meeting of the Berlin Society of Psychiatry and Neurology, held Nov. 13, 1899, a meeting attended by Oppenheim, Jolly, and many others. Two cases were reported at the 25th annual meeting of the American Neurological Association in 1899 by Sinkler, who was the first to demonstrate the facial appearance of a patient by photographs. The year 1900 witnessed a great outpouring of literature on the subject. The disease became widely recognized in the minds of the British and American medical profession, chiefly owing to the paper by Campbell and Bramwell in *Brain*, a standard neurological journal. A typical case, seen at the Massachusetts General Hospital, was described by Paul in 1900.

COUNCIL ON FOODS AND NUTRITION

COUNCIL ON FOODS AND NUTRITION

This article was written at the request of the Council by the worker who first described kwashiorkor as an entity—Dr. Cicely D. Williams. Its publication in THE JOURNAL *will direct attention to this syndrome, which is known to exist in wide areas of the world—Africa, Latin America, Mexico, Central America, the Caribbean Islands, and elsewhere—and which may occur, but be unrecognized, within the boundaries of the United States and its possessions.*

JAMES R. WILSON, M.D., *Secretary.*

KWASHIORKOR

Cicely D. Williams, D.M. (Ox.), F.R.C.P., D.T.M.&H. (Lond.), Mona, Jamaica, B. W. I.

The study of child health is of comparatively recent growth in the scientifically advanced countries. It is still rudimentary in the countries that are relatively underdeveloped. In most tropical areas, the first duty of the "imported" doctors was to care for the imported population and then to control the major epidemic diseases that might endanger the people as a whole. Preventive medicine was mainly concerned with mass methods. Gradually, more of the indigenous people began to appreciate western medicine and began to accept and then demand treatment.

Tropical diseases are, in fact, mainly due to poor standards or personal hygiene and poor environmental conditions—not to climate. But tropical medicine is overburdened with entomology and laboratory pathology. Even now, courses offered in tropical medicine contain little reference to children. Books on tropical medicine are equally negligent, although it is well known that infancy and childhood are the ages at which adverse environment is most devastating.

When child centers were first started in tropical countries, they were looked upon as amateurish and fanciful. Many persons regarded them as unnecessary frills and not as the basic need of a medical service. Few persons realized that "the survival of the fittest" is a misapplied cliché. It was not recognized that the same conditions that will kill 30% of the babies in the first year of life will also produce a large proportion of persons with damaged lives who will be a burden for years and perish at a later date.

THE DISEASE IN AFRICA

Child welfare clinics were started by the colonial medical service in the Gold Coast, West Africa, during the second decade of this century. The original idea was that they should prevent disease but not cure it. It did not at once occur to anybody that this type of child welfare center was designed to meet only felt needs in a population that already possessed an efficient and acceptable curative service during an era when the value of follow-up was not appreciated. These centers soon became extremely popular, but it was obvious that the demand for treatment of sick children was over-

whelming. As soon as the Africans discovered that here were physicians who were particularly interested in children, they brought them in swarms. Children's hospitals were built in the two main towns, Accra and Kumasi. The legend was that these hospitals would only take in patients with minor nutritional disease, while patients with serious disease would be sent to the general hospitals. The parents would accept treatment, including admission to a hospital, at the children's centers, where they had learned to know and trust the staff, but many simply would not consider going anywhere else. Fortunately, the mother always insisted on staying in the hospital with the child. "Rooming in" and "demand feeding" were practiced in the Gold Coast long before they were discovered in other countries.

The doctors in charge of these children's centers were faced with many problems. They were officially urged to do prevention rather than treatment. But they realized that disease cannot be prevented unless one knows something about what one is trying to prevent. Their European experience and books were useless, and opportunities for laboratory investigation were minimal. But there was much to be learned simply by observing the children and by talking with the parents and with the African staff. Once they found that the physicians were interested in children, their cooperation was boundless.

It was soon evident that malnutrition was a big problem, though poverty was not. There was little real shortage of money or of food, but there was deep ignorance of how a child should be fed, of how to exploit available resources, and of how to preserve supplies from the season of plenty to the season of shortage.

Few patients presented a simple problem. The doctors had been brought up to avoid a "double diagnosis." Malaria, however, was almost universal, and the incidence and mortality were highest at the ages of 6 months to 4 years. Roundworms were common, and up to 90% of some groups were infested. Yaws, scabies, tropical ulcers, septic skin infections, diarrhea, dysenteries, and respiratory infections were all abundant. Sometimes a patient would be suffering from six or eight of these conditions all at the same time. It was under these circumstances that cases of a spectacular and often fatal form of disorder began to sort themselves out.

In 1927, Dr. R. A. W. Proctor [1] had written in the *Kenya Medical Journal* of a hitherto undescribed condition: "The disease occurs only in quite young children; the child is almost always of an extraordinarily light color and is usually brought up on account of swelling of the feet. The only history obtainable appears to be that in a number of cases there had been slimy motions for some time. As the disease progresses the child becomes paler in color and the pigment appears to be concentrated into a curious black desquamation which is most noticeable on the arms and legs; cracks and sores are often seen at the bends of the elbows and knees, and there may be general edema. The child, as far as my information goes, nearly always dies."

In 1906, Czerny and Keller [2] described a condition among children in Germany due to excessive carbohydrate in the diet, which they called *Mehlnahrschaden.* The disease was obviously close kin to the one we were seeing in the Gold Coast. This was recognized by Waterlow [3] after extensive research some years later. In 1932, a similar condition in West Africa was described by Dr. M. Lieurade [4] under the title "Les enfants rouges du Cameroun." Unfortunately, none of these publications had made their way to the Gold Coast, and we were unaware that the condition existed in other parts of the world.

The disease was first noted in the south, or "colony," part of the Gold Coast. Since the supplementary food for children in that area was nearly always some form of white maize and since some of the features of the disease were comparable to pellagra, it was thought that the maize might have a causative relation. The first article on the subject was published under the title "A Nutritional Disease of Childhood Associated with a Maize Diet." [5] Later, it was found that the condition was also prevalent in Ashanti, where maize was not the only supplementary food; therefore, in a short summary for *Lancet,*[6] it was called kwashiorkor. This cumbersome word was merely a confession of ignorance. It was the name given to the disease by the Accra people, to whom it was well known. Some say the word means "red Kwashi." Kwashi is the name for a boy born on a Sunday, but it is used as a generic name as we would use Johnny or Tommy. Even now, in Jamaica a simple country fellow is referred to as "Quashie." In this name, I believe the redness refers to the raw areas where the skin has peeled off in the severe and acute cases and not to the hair. MacPherson,[7] on the other hand, believes that, since red is the color of magic and these children are regarded as possessed, the "redness" refers to the *mystique* of the disease. One of the conditions governing the selection of a paramount chief was that he should not have red hair. The supreme virtue of the word kwashiorkor is that it does not make any unwarranted assumptions with respect to etiology or pathology. It was remarked in a *Lancet* editorial that it has the merit of neutrality.

In 1934, Dr. H. S. Stannus [8] wrote an article to the effect that the disease was, in fact, infantile pellagra. Some physicians, with first-hand knowledge of the disease, accepted his assumptions. Further study has generally led to the opposite conclusion; frank cases of the two conditions cannot possibly be confused. But it is obvious that in all types of nutritional disease, mixed cases can occur, and it may be impossible to decide which of the conditions is the dominant type. Soon after this, Dr. H. C. Trowell, working in Kenya and Uganda, began to investigate the condition.[9] At first he accepted the diagnosis of infantile pellagra, and later adopted the name malignant malnutrition. He has now reverted to kwashiorkor. Trowell has made invaluable contributions in the study of the disease and in bringing it to the notice of physicians in many parts of the world. Achar [10] prefers the name nutritional dystrophy.

In recent years kwashiorkor has been described as occurring in every part of Africa, India, China, the Philippines, Fiji, Indonesia, Malaya, South and Central America, the Caribbean Islands, and in Hungary and Italy. In such diverse backgrounds and food patterns, it is obvious that there are multiple factors that may complicate and variegate the picture. The areas where rice or wheat form the main bulk of the diet do not appear to be as subject to the disease as those where maize and root vegetables, such as cassava, yams, sweet potatoes, and Colocasiae are the staple foods.

In 1949, the joint committee on nutrition of the Food and Agricultural Organization (FAO) and World Health Organization (WHO) reported as follows: "One of the most widespread nutritional disorders in tropical and sub-tropical areas is a syndrome, at present ill-defined, known by various names such as 'kwashiorkor,' malignant malnutrition, poly-deficiency disease, 'm'buaki,' 'syndrome dépigmentation oedeme,' infantile pellagra, etc. The committee is satisfied that this condition is not identical with classical pellagra and suggests that the name 'infantile pellagra' should not be used for this syndrome. It appears that the highest incidence of the disease occurs in infants and young children and that the mortality rates in some parts of Africa are disturbingly high." The committee "recommends that WHO conducts an inquiry into the various features of kwashiorkor . . . to define the clinical features and to study the food habits of the population." As a result of this, Drs. J. F. Brock and M. Autret made an investigation and published a report on the condition as it was seen in Africa.[11]

The disease is obviously not a simple one, and it is impossible to produce a simple definition to please all tastes. It is probably due to malnutrition and most likely to some protein defect or defects. There are bound to be many local variants. The presence of intestinal parasites, of mineral, vitamin, or other defects, and concurrent infections will produce modifications. When the disease was first described, the severe, spectacular cases were the main theme, physicians are now able to detect the early cases—the slight swelling of the dorsa of the feet, the slight enlargement of the liver, the mild anorexia, the apathy, and the coldness of the extremities—which in the early days would have been missed or underrated. In fact, a name means very little except to classify a certain conception. Until the pathologists and biochemists can give us more precise information about the defects, we may as well accept the word kwashiorkor in all its cacophony.

In recent years the literature on kwashiorkor and kindred conditions has reached vast proportions. Now that it is receiving worldwide attention and there is more opportunity for exchange of information, it is possible, to some extent, to keep track of the observations in a number of countries. But much confusion is due to misquotation, failure to study references, and the inaccessibility of relevant literature. An excellent summary by the late Professor Altman, published in 1948, is useful.[12] He gives 84 references to literature from 12 countries up to that date. Brock and Autret[11] give a wide but incomplete bibliography. In recent years, most of the papers are reviewed in journals of nutrition and of tropical medicine. They are mainly neglected by the pediatricians, who have not yet attained any degree of geographic versatility.

HISTORY

Invariably the history is of a low protein diet. In the Gold Coast the disease is described as "the sickness of the deposed baby"; that is, it is associated with weaning. In some cases, the breast feeding was inefficient. The mother was sick or was dead, and breast feeding was undertaken by an aunt or a grandmother who had not had a baby for some years. In one case, it was a grandmother whose youngest child was 19 years old. In East Africa, where the condition is much commoner and where the average diet of the population is much worse, the babies start to show the symptoms when they are still being breast fed. This also applies to India. Thus far, the composition of the mothers' milk has not revealed consistent abnormalities, but this subject requires more attention. Certainly, in many of the early cases, the mother's diet has been noticeably poor in proteins. In many parts of Africa, there is little or no cow's milk to be had; in India, even if the cow's milk is available, the animal may be in exceedingly poor condition, and the milk is again from a malnourished source.

The fact that many other children in the community have a low protein diet and have mothers who have a low protein diet and yet do not suffer conspicuously from kwashiorkor is typical of most nutritional stories. There is obviously enormous individual variation in capacity to absorb and utilize the available diet. It often happens that the disease does not become evident unless some added factor such as roundworm, hookworm, or bronchitis is acquired and tips the balance. It is suspected that some persons recover without obvious external signs but with liver damage that may be crippling or fatal in later years.

RETARDED GROWTH AND MENTAL APATHY

Growth is always retarded, even though the child, at first, appears neither emaciated nor ill nourished. In the areas where the disease is rampant, it is found that the weight curves of Kampala (East African),[13] Gambia,[14] and West Indian[3] babies follow the same curves as those of European infants up to about four months and then begin to fall. This symptom, of course, is not specific. If children are regularly observed, as they are at welfare centers, growth failure will be found to precede some attacks of beriberi[15] and many other diseases.

Peevishness and apathy may be the first sign to develop. The child becomes stolid and indifferent. He shows none of the interest and liveliness that are normal to a well-nourished child. If disturbed, he becomes resentful and peevish, but he shows no vigor in his resentment. As the disease progresses, he sinks more deeply into a state of depression and resentment. One of the earliest signs of improvement is that he begins again to show complaisance and then interest or pleasure.[16]

EDEMA

Edema may be a very early sign. Sometimes, in the Gold Coast, the mother would begin to notice a very slight swelling on the dorsa of the feet and then of the hands. When the edema is more generalized, it may mask a severe degree of emaciation. Generally the edema is more marked on the extremities than on the trunk. When there is edema of the face, it is generalized. There is no marked puffiness of the eyelids, as in nephrosis, and there is no marked pendulousness of the cheeks, as in ascariasis. Edema does not usually become extreme as it may do in cases of nephrosis and beriberi. In fact, an injection of thiamine can be used as a diagnostic measure in cases of doubt or when a mixed condition is suspected. Beriberi will respond promptly with a diuretic deluge. The edema of kwashiorkor generally disappears slowly as the child recovers, but in most fatal cases it also decreases before death. Edema may be present at the same time as emaciation. The moribund patient is not always edematous and not necessarily emaciated.

HYPOALBUMINEMIA

In the early descriptions of this disease, there was no opportunity to record blood chemistry; however, various observers have made extensive studies. In the majority of cases it is found that the serum albumin is low (down to 2 gm. per 100 cc.), while the globulin is extremely variable. It has been found that many persons, even children, may have the same, or almost the same, anomalies of serum proteins, without having obvious kwashiorkor.[17]

Dean[18] has summarized the blood findings: "In the seru of these children the total proteins and the albumin we considerably below normal in amount but the globulin wa high. . . . The blood urea was little more than half th normal figure and the total cholesterol was also very lo The ratio of free to total cholesterol, which depends on a enzyme, a cholesterase, whose activity was presumably greatl reduced, was very high, and other enzymes seemed to b affected in the same way; alkaline phosphatase, cholinesteras amylase, and total esterase were all low. . . . The heigh [of globulin] at the start and at the end of treatment are bo due to γ globulin, the α and β globulins are less affecte The albumin rises more than the total globulin so that th albumin/globulin ratio rises, but it seldom goes over unity

Anemia is not an essential part of the disease. In man cases it is insignificant. But children very often react malaria with rapidly developing anemia,[19] and the anem that accompanies roundworms in young children can be severe as that seen in cases of hookworm infection.[20]

DYSPIGMENTATION AND DERMATOSES

"Dyspigmentation" is preferred to "depigmentation," sin the hair not only is bleached but is also changed to a reddis color. The hair changes are not specific. It is well know that any form of wasting disease may affect the color an texture of the hair. Exposure to sun, wind and rain, an salt water may also produce changes that are very simila In West Africa there are persons of pure African ancest who have red hair and are in good health.

In East Africa the hair changes are common and rang from slight softness, or reddish tone, to hair that is dr straight, sparse, staring, and red, pale, or bleached. In India children the hair may be reddish, gray, or white. In man cases of mild nutritional defects, a slight reddish fringe ma be seen over the forehead and around the temples. In som of the very acute cases of kwashiorkor seen in the Gol Coast, the hair changes were not conspicuous. Some of thes cases were rapidly fatal. It may be that the hair changes ma partly depend on a variable mineral depletion. They certainl vary enormously with racial background. It is important t regard the hair changes in the right perspective. If a pigmente 2-year-old baby who has not been exposed to the element and who is not suffering from tuberculosis or another wastin disease has hair that is dry, pale, sparse, and staring, he i probably suffering from some degree of malnutrition of th kwashiorkor type.

The skin changes are the subject of much controversy an should be considered together with other nutritional dermatoses. In the Caucasian race it has long been recognized tha unhealthy persons will not pigment normally on exposure to sunlight. In the pigmented races also, the color and texture of the skin are an important signpost. In many children of pigmented races, wasting diseases are accompanied by pallor. In cases of kwashiorkor this is often well marked. Trowell has noted that very often the pallor on the face is more marked than on the rest of the body. In many persons of pure Negro ancestry reddish hair and skin will develop.

The cases referred to as kwashiorkor by the Accra people were in children who had dark thickened patches of skin on limbs and back, which peeled off, leaving a pink, almost raw surface. Later it was noted that in some countries children seemed to be suffering from the same type of disease, but the skin did not proceed to this dramatic development. In some cases the perineum was the only, or the main area affected. "Crazy pavement"[5] has often been used to describe this condition, but it is not particularly apt. I would suggest instead "peeling pellagroid" to indicate the depth of the desquamation. In fact it is extremely difficult to handle these children without major trauma. Besides soft thickened patches that on peeling leave a raw surface, there is often a generalized desquamation, extending over the trunk.

Severe cases are often accompanied by angular stomatitis and desquamation at the outer canthi, which may be due to some degree of concomitant ariboflavinosis. There may also be photophobia and corneal ulceration. There is often glossitis and buccal ulceration. In the countries where kwashiorkor is commonest, there are also many cases of cancrum oris, and the two are sometimes found in the same person.

In areas where there is much malnutrition, often a glossy dryness is found on the extensor aspect of the tibia. This proceeds to a superficial cracking of the skin and, in the later stages, to a pigmented mosaic appearance that is found mainly in growing children and in adults. The same may appear on the forearms. But this condition is found in places where kwashiorkor is rarely seen; of course, mixed conditions may occur.[21]

It may be that variations in the fat or some mineral content of the diet are concerned in the development of the skin changes.[22] In some instances the skin changes are inconspicuous; in others they are startling. One of the most distinctive points in diagnosis lies in the photosensitivity of the skin in pellagra. In kwashiorkor the lesions may appear on, and be confined to, the areas protected from the light.

GASTROINTESTINAL DISORDERS

Gastrointestinal disorders again are inconstant and irregular. The earliest sign is anorexia. The patient may refuse food or may show a lack of initiative with respect to food. The anorexia may become an extreme problem in treatment. Vomiting is common. Sometimes a child will stolidly go through a meal, quietly vomit the whole lot, and then curl up in bed exhausted and withdrawn. Attacks of diarrhea may alternate with constipation. The stools may be merely loose and slimy or may be those of steatorrhea. There is rarely any blood. Attacks of diarrhea and/or vomiting may delay recovery. Nutrition must be improved with caution.

Ascariasis is common in many parts of the world where kwashiorkor is found. Some observers hold that one depends on the other. Until the present time not nearly enough attention has been paid to the devastating effects of ascariasis on the young child.[23] The infection can be acquired at any moment after birth from the dirty hands of the mother or other attendant, whereas ancylostomiasis does not generally occur until the child is old enough to toddle in places where larvae lurk. One or two male ascarides in the intestines of a young baby may produce no ova but may cause havoc in the digestive system or even death. In countries where there is a high rate of ascariasis, adults who may harbor many helminths in apparent symbiosis will be found. But the effect on the children, who have not yet acquired an immunity, is very different. If a child gets sick, the roundworms often leave the host. In an acute illness, the worms can be observed leaving by any of the orifices and often cause intestinal obstruction if they are in large numbers. In a chronic disease, the "rats may have left the sinking ship" before the child comes under observation. Ascarides may be a factor in the case, although all the worms have departed, and they are certainly an important factor in a large proportion of the cases of kwashiorkor in certain parts of the world. Ascarides may cause liver abscesses and possibly other liver damage.

PATHOLOGICAL CHANGES

Pathological changes are mainly in the liver, and enlargement, fatty infiltration, necrosis, and fibrosis occur singly or in combination. The typical necrosis is cellular, that is, seen only on microscopic section.[3] The liver is generally enlarged. It will go through a stage of considerable enlargement, but in many advanced cases it is shrunken, soft, and so fatty that it is almost diffluent.

There is great variation in the size of the normal liver. Mitchell and Nelson[24] state: "in the newborn infant the liver edge is about 5 cm. below the costal margin in the right midclavicular line. . . . The lower border of the liver may be palpable normally below the subcostal margin throughout childhood." Judging by the frequency of diabetes and Fröhlich's syndrome, American children must suffer more from overfeeding than from underfeeding. Apparently both forms of malnutrition may produce enlarged livers. Most observers in Europe would not agree that the average child of 18 to 24 months had a liver below the costal margin, while in malnourished countries a palpable liver at this age must be regarded as suspect. It is difficult to determine exactly what amount of fat in the liver of a child may come within normal range. Waterlow[25] gives 4 to 5% as normal, but he has found that children with kwashiorkor may have up to 30% of fat even before there are gross external signs.

In the earlier studies of kwashiorkor[26] a fatty infiltration of the liver was the most constant and the only conspicuous defect. In some of the more chronic cases, the fat seemed to be disappearing, and the liver was flabby, with extensive necrosis. In most of the later work the changes in the liver have been far more carefully studied. Waterlow[27] has found all stages of fatty change in the West Indies; however, the babies in the Gambia began to have fibrosis at extraordinarily early stages, without any previous fatty degeneration. Jelliffe and Silvera[28] have found fatty livers present in the early weeks of life long before other symptoms had developed, so the disease may start as intrauterine malnutrition. With the development of the techniques of liver biopsy, it is now possible to study these diseases far more accurately, and this will lead to better definitions and more specific treatment and prevention. Waterlow[27b] first described the atrophy of the external secretory cells of the pancreas. Davies,[29] in an important study of the pathological changes, described fibrosis of the pancreas as well as of the liver. He believes the pancreatic lesion to be the primary one.

OTHER FINDINGS

Trowell and Thompson[30] have done some extremely careful and interesting work. Taking edema, without obvious renal or cardiac cause, hair changes, and subnormal weight as the criteria for diagnosis, and using normal African children for comparison, they found a well marked reduction in amylase, lipase, and trypsin that was reversed with a high intake of milk protein. Veghelyi,[31] working in Budapest, has also described the defective enzymes.

In the Gold Coast patients coldness of the extremities was very important. Even in an equatorial climate this sign was conspicuous. Keeping the child warm was found to be one of the most important points in treatment of all the advanced cases. A radiant heat cradle would facilitate recovery in no uncertain degree.

LATE RESULTS AND DIFFERENTIAL DIAGNOSIS

Cirrhosis and carcinoma of the liver are common in some of the countries where kwashiorkor is found. What the exact relation is between these conditions has not yet been proved. Infantile hepatic cirrhosis developing into portal cirrhosis, so common in India and Ceylon,[32] and serous hepatosis, probably related to it, described by Hill[34] in Jamaica, are also very likely to be of nutritional origin. The place of infection, such as infectious hepatitis, in this picture is not yet clear. In these cases, the patient looks well nourished and cheerful. Ascites may be an early sign. The liver is enlarged and hard, but biopsy shows no fat. There is a typical exudate that leads to fibrosis. Of course, some mixed cases occur.

Brock and Autret[11] give the following definition of the disease: "A nutritional disorder occurring particularly in the age period six months to five years . . . associated with low protein diet.

The fundamental characteristics of the syndrome are:

1. Retardation of growth.
2. Dyspigmentation of hair and skin.
3. Edema usually associated with hypoalbuminaemia.
4. Pathological changes in the liver including one or more of the following—fatty infiltrations, necrosis, and fibrosis.
5. A heavy mortality if untreated or incorrectly treated.
6. Nutritional dermatosis—occurs in a variety of patterns, but may be absent.
7. Gastrointestinal disorders. These are variable and include one or more of the following—anorexia, digestive upset, diarrhea, mild steatorrhea.
8. Peevishness and mental apathy.

Unfortunately the order is illogical, and this study only refers to Africa; but the statement will serve as a basis for discussion.

Pellagra is the main condition with which confusion is likely to arise. It cannot be stated too often that there is nothing to prevent the finding of mixed conditions. The differential diagnosis was previously stressed,[34] but it may be useful to repeat it.

	Kwashiorkor	Pellagra
1.	Common in young children	Rare in young children
2.	Well-developed dermatitis indicates a severe degree of the disease	Severe dermatitis may occur before constitutional signs develop
3.	Rash has no relation to exposed areas	Skin is photosensitive. Rash is only on exposed areas and *will disappear if skin is protected*
4.	In early stages skin may be bleached. No well-marked *edge to rash*	Early stage of rash is red, swollen, and irritating, with *well-marked edge*
5.	In later stages skin is dark, soft, and crumpled and strips easily, leaving raw surface	In later stages there is a dry, branny desquamation
6.	Disease may develop in patients on a diet containing some milk	Disease not described with milk diet
7.	Large mortality if untreated	Rarely fatal

Kwashiorkor differs from total undernutrition in that the actual intake of calories may be sufficient, but the excess of carbohydrate in relation to protein is damaging. Other factors are important, such as the various amino acids and the proportion in which they appear in the diet. The disease differs from marasmus in that severe illness and death may take place long before there is emaciation.

Hunger edema generally decreases with rest and often increases after a balanced diet has been started, but has many features in common with kwashiorkor. It is, in fact, a part of the syndrome, but it can exist in adults with a normal liver and with serum proteins only slightly altered. Kwashiorkor is associated with hypoproteinemia.

MORTALITY

In the early days, when the disease was not diagnosed until its late stages, the mortality was high, up to 80%, but since then the condition has been more extensively studied and the mortality reduced. In certain areas the hospitals are still confronted with numbers of patients in the late stages of the disease, many of whom die of it or of some intercurrent condition. In these areas too, it is difficult to maintain follow-up. Even patients who leave the hospital vigorous and, apparently, in perfect health may, a few months later, die of the same disease.

TREATMENT

In early days[35] it was found that patients would respond to milk in the diet, and now it is proved that milk protein is curative if irreversible changes have not already set in. Achar[10] has had good results with blood transfusions and concentrated human serum. Most physicians have found it essential to reduce the edema before much intravenous nutrient can be given. In this the radiant heat cradle is most useful, and when possibility of beriberi is a complication, thiamine injections should be tried. Protein hydrolysates have been used with good but variable results.

Feeding often presents great difficulties. If the child is still breast fed, the mother's diet must receive attention and supplements must be given to the child. If the child is weaned, it may be extremely difficult to induce him to take any other food than the boiled banana (*matoke*) or cornmeal or food to which he is accustomed. He will often refuse to dr milk. In these cases, milk protein in powder form can mixed with the accustomed food until the appetite impro In South Africa[32d] the Gillmans reported good results w dried hog stomach, but this has not been found successful other places. Nicotinic acid has been reported in some ar to improve the skin condition, but this again is not a univer finding. It must be remembered that the skin condition of improves when the patient does not. Also that in some patie who die, the skin condition may show marked improvem before death, even without nicotinic acid. Assessing result difficult, because it is not possible to compare relative c ditions when the child is admitted to the hospital. In cases severe anorexia a nasal tube with a slow drip may be used

It is important to remember that much depends on in ligent and devoted nursing. Warmth, interest, and encoura ment are needed, and patience and persistence on overcom the anorexia. Small, frequent meals should be given, will high proportion of milk protein and, at the beginning, v little fat. Food yeast or grated cheese added to the milk r make it more acceptable. Dean[33] finds that the patients Kampala were intolerant of lactose, glucose, sucrose, maltose but that *matoke,* boiled green bananas, provide more successful source of carbohydrate. Dean also found t soybean protein could be used instead of milk. This is exceedingly important discovery for countries where milk unobtainable or in short supply.

Besides careful attention to general nursing and to the other deficiency diseases must be treated. Anemia, berib and ariboflavinosis are not uncommon. Malaria must be cluded. Platt[36] is of the opinion that these children car tolerate antimalaria drugs very well. This also applies anthelmintics, and deworming must be carried out with greatest caution. Only by efficient follow-up work thro outpatient clinics, dispensaries, and welfare centers in c touch with the hospitals can permanent cures be clain It is a waste of time to investigate these diseases or to c them in hospitals if teaching in the homes and parent e cation is neglected.

PREVENTION

Kwashiorkor is prevented by a reasonably good diet mother and child. It is a melancholy reflection on the defects of tropical medicine that a disease so spectacular so widespread should have been ignored for so long. We hunger and the rise of communism are the two things m dreaded in the free world. The two are interrelated, and prevention of kwashiorkor is concerned with the same pr lems. Investigations on this disease are by no means compl but we know enough to cure the disease in 95% of cases to prevent it in everyone. While many of the most able in lects are at work finding out more scientific details of path ogy, there are extraordinarily few attempts being made methods of insuring prevention. Yet if we can prev kwashiorkor, we can also prevent world hunger and ot evils.

Prevention lies in teaching the parents what food to prov for themselves and their children. In many areas this food not available at present; only comprehensive undertaki that will coordinate agriculture, education, and health can of any use. In many other areas it is ignorance, prejudi and wastefulness that is responsible—not poverty.

Disease control projects, relatively easy to apply, h absorbed both the national and the international agencies. T result has been vast increase in populations, without comparable improvement in the standard of living or e cation. Blind craving for spectacular results is leading strai to disaster. It is time that medicine realized that its duty to aim not only for healthy minds in healthy bodies but healthy persons in a healthy community.

If the medical leaders had any sense of proportion, th would be changing over as rapidly as possible in order adjust the balance before disaster overtakes man. They wou devote their best men and their largest finds to the co structive side of medicine—education toward healthy livi physical and mental, training of personnel, and follow-up which is social medicine.

Many persons are doing research in electronics and in the more abstruse sciences. In order to make a balanced world, we should provide far more persons who can and who will experiment in methods of propagating improved mental and physical health. We worry a great deal about the persons we want to liberate from political tyranny, and we ignore those we could and should liberate from the tyrannies of dirt, ignorance, and hunger.

In many parts of the world, maternal and child health work is now established, but too often it is grossly inadequate, both in extent and intent. It is the method par excellence of reaching the parents, the homes, the schools, and of improving the nutrition. This type of work cannot be done on any preconceived pattern. It must be adjusted to the needs and resources of each country. It needs the most careful observation, evaluation, and planning if results are to be achieved. Too often this work is regarded as a mere appendage, to be left to the uncertain care of voluntary societies. It may be scorned by the hospitals, directed by health officers who have no interest in it, and carried out by nurses who have little or no training in pediatrics, nutrition, or social dynamics. "Social welfare" is often engaged in expensive failures because it ignores the needs, the techniques, and the opportunities of health and nutrition.

Child health work is often discouraged by those who are most apprehensive of overpopulation. They ignore the obvious; persons who are interested in the future of their children do not breed recklessly. The countries in which the care of children is most emphasized are not those with an excessive birth rate, nor do they breed weaklings, mental or physical.

All over the world the medical authorities have been dazzled by the ease and by the results of mass methods of prevention and by the heroics of therapeutic miracle. It is urgently necessary for the leaders of medicine to cultivate that rare and most necessary factor, common sense, and to decide, with McCollum, that society must measure its well-being in terms of the health of its children.

COUNCIL ON PHYSICAL MEDICINE AND REHABILITATION

REPORT OF THE COUNCIL

The Council has authorized publication of the following article.

Ralph E. De Forest, M.D., *Secretary*.

INTRACERVICAL AND INTRAUTERINE DEVICES

Some contraceptive methods are not health hazards, whereas others endanger the well-being and health of their users. The booklet, "Apparatus Accepted by the Council on Physical Medicine and Rehabilitation," lists diaphragms and sheaths. When these products are used correctly, the evidence available indicates that they are not health hazards.

In general, intracervical and intrauterine devices are hazardous to the user. These devices are of various shapes and styles, but all have in common a cap that is held over the os uteri externum by a stem that flares in one way or another within the uterus to hold the pessary in place. Pessaries can have a legitimate use and can be highly effective for therapeutic purposes as a means for obtaining drainage, when conditions so indicate.

There can be little doubt, however, that these devices are promoted by some firms primarily for the prevention of conception. One such device has a stem with three conical enlargements aligned so that their apexes point into the uterus. At one end are two prongs and at the other end is a soft rubber button about the size of a nickel. The entire pessary is covered with a coating of rubber. The advertising does not state directly that the pessary is used for contraception. To circumvent this direct claim, the advertising is subtly worded to imply such use, as for example:

> The valvelike action of the cones impedes the progress of flagellate organisms. These organisms become exhausted, their vitality is lowered, their motility reduced and they perish.
>
> The cones, by exerting a gentle pressure upon and by being in constant contact with the ciliated epithelial lining of the cervical canal, interrupt the normal wavelike motion which sweeps inward, thus again impeding the advance of organisms which depend upon this ciliary motion for progress.

Another firm's illustrated catalogue of items for planned parenthood includes diaphragms, contraceptive jellies and creams, diaphragm inserters, and fitting rings and devotes one-half of a page to describing a pessary very similar to the one just described.

The use of stem pessaries has been discontinued by most physicians because of the danger of uterine injury and pelvic infection. Nevertheless, there still appear to be some champions for the contraceptive use of these devices. Although the evidence is not conclusive to indicate that carcinoma has been developed through the use of these devices, the evidence is quite clear to show that uterine and cervical infections may be traced to their use. Pelvic inflammatory diseases and abscesses have necessitated surgical intervention. The metal cervix pessaries have caused endometritis and obstruction to drainage resulting in widespread pelvic infection. Cellulitis may develop from a lost stem which frequently works its way farther upward into the uterus and produces a foreign body reaction. Furthermore, stems may perforate the uterine wall or uterine blood vessels and become embedded so as to create a pathway for the ascent of bacteria into the uterus. Pregnancy may occur in the presence of an intracervical pessary, and if the device remains in place longer than one month, it is likely to cause abortion.

The Council on Physical Medicine and Rehabilitation condemns the use of these devices as a method of achieving contraception because of the lack of evidence to indicate that the device is "nonirritating," "noninjurious," or causes "no troublesome after-effects."

APPARATUS ACCEPTED

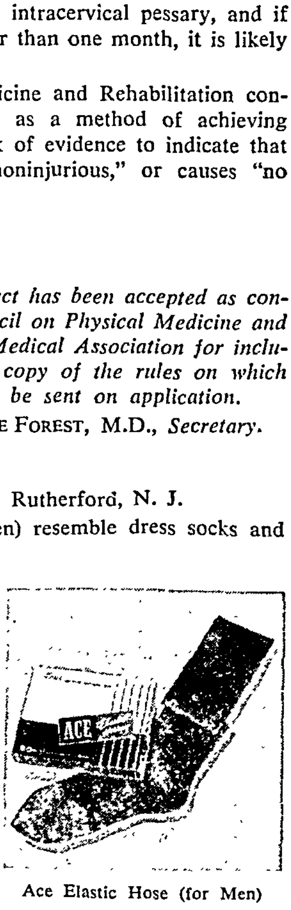
The following additional product has been accepted as conforming to the rules of the Council on Physical Medicine and Rehabilitation of the American Medical Association for inclusion in Apparatus Accepted. A copy of the rules on which the Council bases its action will be sent on application.

Ralph E. De Forest, M.D., *Secretary*.

Ace Elastic Hose (for Men)

Becton, Dickinson and Company, Rutherford, N. J.

The Ace Elastic Hose (for Men) resemble dress socks and extend to a level just below the knee. They are made of nylon-covered rubber and have complete feet. The weave is described as a two-way stretch. The toe is made of nylon only (no rubber) and the heel of double thread nylon-covered rubber to provide elasticity. The cuff or self-gartering portion of the stocking is made of nylon-covered rubber, double thickness, and has a minimum width of 5 cm. (2 in.) to prevent binding. For the realization of the intended beneficial effects, a proper fit is essential, especially since too tight a fit at the upper end of the stocking will impede venous return flow. Since this stocking ends below the knee, its usefulness in persons with varicose veins is limited to lesions below that level.



Ace Elastic Hose (for Men)

SURVEY OF PHYSICIAN ATTITUDES

The Council on Medical Service, through its Committee on Prepayment Medical and Hospital Service, is now conducting a survey of physician attitudes concerning voluntary health insurance. With voluntary insurance programs of many types insuring increasing numbers of persons, the attitude of physicians is most important to its continued growth and success. It is the physician who certifies whether a person is disabled and thereby eligible to receive insurance benefits. The physician is also the one who certifies when the patient recovers, when he returns to work, and when he ceases to receive those benefits. In the realm of hospital, surgical, and medical expense benefits the physician is again the one who certifies the need for hospitalization, surgery, etc. In addition, the physician derives a substantial source of his personal income by virtue of insurance benefits that assist insured patients in financing their health care.

There is no uncertainty about the attitude of the vast majority of practicing physicians concerning the relative merits of the many forms of voluntary health insurance over any compulsory tax scheme. Likewise, there is little doubt relative to the opinions of spokesmen for certain nonmedical and noninsurance groups concerning their attitudes about what voluntary insurance can and should accomplish. Insurance, like medicine, is an exacting science and can accomplish only that which comes within the scope of its natural limitations.

Many questionnaires and many opinion surveys have been designed since the advent of health insurance. None, apparently, has attempted to gather information that would indicate the attitude of physicians concerning certain aspects of voluntary health insurance. This is the purpose of the current survey. The Bureau of Medical Economic Research is mailing the questionnaire to avoid the possibility of having the same physicians receive more than one type of questionnaire currently emanating from American Medical Association headquarters.

Health insurance, at times, is subjective. It has created a vocabulary comparatively new to many who have been interested in the topic. The same terms and phrases convey different meanings to different persons according to their own experiences or to the sources of their information. Considerable care has been taken in preparing the current questionnaire to minimize misinterpretations and maximize the accuracy of tabulating opinions in a difficult field. Among other things it is necessary to know to what extent insurance plans may affect the traditionally confidential relationship between the patient and the physician. The survey is also designed to learn how physicians feel about the extent to which insurance involves them in the realm of service benefits and in their financial relationships with patients and how they feel toward the different types of generally available insurance plans.

Although the survey is sponsored by the Council on Medical Service through its Committee on Prepayment Medical and Hospital Service, the questionnaire itself was prepared after deliberations with the Bureau of Medical Economic Research and consultations with a Committee from Blue Shield Medical Care Plans and other groups. The success of any survey is contingent on an adequate sampling coupled with sufficient returns from which to draw reliable conclusions. For the most part, the questionnaire is designed to facilitate completion with a minimum of time and effort. It is to the advantage of the physicians who receive these questionnaires mailed on a random sampling to study them carefully, complete them to the best of their ability, and return them promptly. In this way they will be more properly represented in committee and national conferences involving health insurance.

BLEEDING ESOPHAGEAL VARICES

Esophageal varices develop secondarily to partial or complete obstruction of the portal blood flow at the junction of the esophagus and cardia of the stomach between the coronary vein, a branch of the portal circulation, and the esophageal veins, branches of the azygos vein of the systemic circulation. Portal hypertension may be one of two types, intrahepatic or extrahepatic, or a combination of both. A high retention of sulfobromophthalein in the blood 30 minutes after intravenous injection, a positive reaction to the hippuric acid test, and reversal of the albumin-globulin ratio all point to the diagnosis of cirrhosis of the liver with intrahepatic portal block. In the absence of these findings, one can assume that the block is extrahepatic. Intrahepatic block may be caused by portal cirrhosis of the Laennec type or by thrombosis of the hepatic veins, the so-called Chiari syndrome. The extrahepatic block may be congenital or the result of thrombosis of the portal vein or of one or more of its tributaries. A combination of the two main types may occur. The syndrome of extrahepatic portal bed block described by Banti is characterized by secondary anemia, leukopenia, splenomegaly, and a tendency to repeated massive gastrointestinal hemorrhages, most frequently associated with ruptured esophageal varices.

Exsanguination from bleeding esophageal varices is a frequent cause of death, particularly in portal hypertension with cirrhosis of the liver. Apparently the portacaval shunt created by the natural anastomosis of the two systems at the gastroesophageal junction is inadequate to prevent increased intraportal tension and development of esophageal varices.

Most workers in this field felt that the definitive treatment of bleeding esophageal varices should be one capable of permanently lowering the tension in the portal system. To accomplish this end, attempts were made to establish a portacaval shunt either by anastomosis of the portal vein to the vena cava or by an end-to-side anastomosis of the splenic to the renal vein. The idea of shunting portal blood into a systemic vein was conceived by Eck, a young Russian doctor, working in Pavlov's laboratory in 1877. He performed successfully an anastomosis between the portal vein and the vena cava in a dog. The recent interest in portacaval shunts in the treatment of portacaval hypertension in human beings has resulted at least partially from the nonsuture method for blood vessel anastomosis devised by Blakemore and Lord.[1] The shunt procedures, however, are too formidable to be safely performed at the time of an acute hemorrhage. A number of methods were therefore attempted to treat the acute massive hemorrhage caused by a ruptured esophageal varix. Among these were ligation of the splenic artery, ligation of the splenic and hepatic arteries, injection of the esophageal varices with sclerosing solution, esophagogastrectomy, total gastrectomy, and esophageal tamponage.

The method of balloon tamponage to control bleeding esophageal varices was first reported in 1930 by Westphall (as quoted by Linton).. Rowntree and associates [2] reported in 1947 successful use of a balloon tamponage in two grave cases of massive bleeding due to esophageal varix. Sengstaken and Blakemore [3] treated successfully 30 patients with acute hematemesis with a nasogastric tube bearing a reinforced balloon. Blakemore [4] recommended leaving the tube-balloon type of tube in the stomach and the esophagus for a week or more, feeding the patient through a third lumen in the tube. The tamponage method, temporarily successful, was not infrequently followed by a recurrence of bleeding after the nasogastric tube was removed. Linton and Warren [5] stress that in patients with signs of impending hemorrhagic shock immediate balloon tamponage should be performed and this should be followed, as soon as the hemorrhage is controlled, by an emergency operation consisting of a transesophageal suture of the varices.

Crile [6] in 1950 reported on seven patients with severe recurring bleeding whom he successfully treated by transesophageal ligation of the varices. He regarded this procedure as a definitive operation rather than one to control the bleeding only at the time of hemorrhage. Linton and Warren,[5] however considered it as a lifesaving procedure at the time of acute hemorrhage but not as a definitive treatment of esophageal varices. They believed that this could be accomplished only by the formation of some portacaval shunt. The time interval between the two procedures, it was felt, should allow for maximum improvement in the underlying liver cirrhosis.

The rationale of the portacaval shunt for the relief of portal hypertension, as pointed out by Blakemore,[4] has been adequately corroborated by portal pressure measurements made at the time of the operation before and after the establishment of shunts. The establishment of an anastomosis of the portal vein to the vena cava or the splenic vein anastomosed end to side with the left renal vein following splenectomy creates a shunt with a low resistance to blood flow. Under these circumstances a large volume of blood will pass from the relatively high pressure portal system directly into the low pressure caval system via the shunt. This results in a marked reduction of the portal pressure. Linton [7] reported on 77 patients who survived the formation of a portacaval shunt; 8 of these patients (10.7%) are now dead and the remaining 69 (90%) are alive and for the most part in good health. Blakemore [4] reported an over-all operative mortality of 17.8% for a series of 140 cases.

Factors influencing operative risk are those of the functional status of the liver and the deleterious effects on the liver of the long-standing portal hypertension. The improvement in the operative results in the last few years is due to advances in the medical treatment of cirrhosis of the liver and the knowledge that a cirrhotic liver fortified with proteins, carbohydrates, and vitamins, if protected against anoxia, is far more resistant to decompensation following surgery than a liver not so supported. The availability of whole blood, plasma, and human albumin for the correction of anemia, restoration of blood volume, restitution of depleted proteins, achievement of potential control of infection, and control of blood clotting all, according to Blakemore,[4] are important factors favoring success with venous shunt procedures.

GASTRODUODENAL HEMORRHAGE

Rappaport [1] has brought into focus a perplexing problem in a way that should benefit many future patients with gastroduodenal hemorrhage. Although in some cases the source of the hemorrhage cannot be found, he is specially concerned with that group in whom lesions presumed to be the cause of the hemorrhage are detected by roentgenogram or gastroscopy and in whom at operation the surgeon is unable by palpation and inspection to detect any lesion. He presents five such case reports of patients in whom a first operation failed to reveal the suspected lesion and a second operation was necessitated by a persistence of symptoms. In two of these cases an adenocarcinoma was found. One patient died three months later and the other recovered and had no recurrence of the hemorrhage. One other patient was found to have a lymphosarcoma and died two years after the second operation. The two remaining patients, one with a lipofibroma and one with a duodenal ulcer, recovered and had no recurrence of hemorrhage. Rappaport concluded that palpation and inspection of the stomach at operation may be unreliable and that when there is strong roentgenologic or gastroscopic evidence of a lesion the surgeon should make a greater effort to substantiate these findings, by opening the stomach if necessary.

MEDICAL NEWS

CALIFORNIA

Symposium on Infectious Diseases.—The California Academy of General Practice in conjunction with Lederle Laboratories will present on Dec. 9 at 10 a. m. a symposium on acute infectious diseases at the Hotel Del Coronado, Coronado. Luncheon will be served. There will be no registration fee.

Pathologists Meet in San Francisco.—The California Society of Pathologists will hold its annual meeting at the Fairmont Hotel, San Francisco, Dec. 5-6. The program, under the auspices of the California Society of Pathologists, the southwestern region of the College of American Pathologists, and the Cancer Commission, will include papers on trace metals and hepatic clearance, a panel on chromatography, and a tumor slide conference.

School Celebrates Anniversary.—The 25th anniversary of the University of Southern California School of Medicine, Los Angeles, was celebrated with a banquet and a convocation on phases of medical education and research, Sept. 24-25. At a dinner at the Ambassador Hotel, Dr. Alan Gregg, medical director of the Rockefeller Foundation in New York, gave an address. At a convocation at the Los Angeles County Hospital, Dr. Paul D. White, Boston, Dr. Hugh J. Morgan, Memphis, and Dr. Arthur L. Bloomfield, San Francisco, were the speakers on whom honorary degrees were conferred for outstanding service in the field of medicine.

CONNECTICUT

Geriatric Study.—Meriden has been selected as the site for an intensive study of the potentials of the aging, according to an announcement by the chairman of the commission to study the potentials of the aging, appointed by Gov. John D. Lodge last July. The final report is to be made on or before July 1, 1954.

Personal.—Dr. Thomas P. Murdock, Meriden, has accepted appointment by Gov. John D. Lodge as the physician member of the state commission, authorized by the 1953 General Assembly, to study the possibilities of the development of a regional professional school including medicine.——Dr. Norman L. Cressy has been appointed director of medical education at Uncas-on-Thames, state tuberculosis sanatorium, Norwich. Dr. Cressy served on the Respiratory Disease Commission, U. S. Army, during World War II, and was previously instructor in medicine, Yale University School of Medicine, New Haven.——Dr. Albert S. Gray, who retired July 1 as deputy commissioner of the Connecticut State Department of Health, has been honored with life membership in the Connecticut Safety Society. The award was presented during the society's meeting on Sept. 28 by Everett W. Martin, past president.

DELAWARE

State Medical Election.—At the annual meeting in Wilmington, the Medical Society of Delaware elected Dr. Hewitt W. Smith, Harrington, president, Dr. Lewis B. Flinn, Wilmington, president-elect, Dr. Glenn W. M. Van Valkenburgh, Georgetown, vice-president, Dr. Norman L. Cannon, Wilmington, secretary, and Dr. Charles Levy, Wilmington, treasurer.

Personal.—A citation was presented to Dr. George H. Gehrmann, Wilmington, medical director of the DuPont Company, by the Malvern (Pa.) Institute for Alcoholism and Psychiatric Studies, in recognition of "the exemplary leadership and courage he has displayed in furthering the treatment, understanding, and welfare of the alcoholic patient and for many years of outstanding service in this cause."

Meeting on General Practice.—The Delaware Academy of General Practice will hold its annual scientific session on Dec. 12 at the Delaware Academy of Medicine in Wilmington. At 10 a. m. Dr. Herman K. Hellerstein, Western Reserve University School of Medicine, Cleveland, will deliver the William J. Urie, M.D., memorial lecture, "The Rehabilitation of the Cardiac," sponsored by Wyeth, Philadelphia. The following program will then be presented:

Drugs and Procedures in Treatment of Peripheral Vascular Diseases, Meyer Naide, Woman's Medical College of Pennsylvania, Philadelphia.
Pathophysiology and Treatment of Congestive Heart Failure, Thomas M. Durant, Temple University School of Medicine, Philadelphia.
Useful Medications in Gastroenterology, James L. A. Roth, Graduate Hospital of the University of Pennsylvania, Philadelphia.
The Electroenterogram, A. Lee Lichtman, New York Polyclinic Medical School and Hospital, New York.
Parenteral Carbohydrate Therapy in Medicine, Jacob J. Weinstein, George Washington University School of Medicine, Washington, D. C.
The Management of Pain, Donald H. Stubbs, George Washington University School of Medicine, Washington, D. C.
The General Practitioner as a Urologist, Elmer Hess, Erie, Pa.

At 7 p. m. the annual banquet and dance will be given at the Brandywine Country Club. The guest speaker, Dr. John S. DeTar, Milan, Mich., speaker of the house of delegates, American Academy of General Practice, will discuss "The General Physician and His Problems."

FLORIDA

Society News.—The Florida Pediatric Society has elected Dr. C. Jennings Derrick, West Palm Beach, president, and Dr. Wesley S. Nock, Coral Gables, secretary-treasurer.

Narcotic Violation.—Dr. James Ryan Chandler Sr., Daytona Beach, pleaded guilty in U. S. District Court at Jacksonville to violation of the federal laws relating to the illegal use of narcotics (USC Title 18, Section 494) and on Aug. 21 was sentenced to serve a term of two years.

Otologic-Ophthalmologic Seminar.—The eighth annual University of Florida Midwinter Seminar in Ophthalmology and Otolaryngology will be held at the Sans Souci Hotel, Miami Beach, the week of Jan. 18, 1954, lectures on ophthalmology being presented Jan. 18-20 and on otolaryngology, Jan. 21-23. A midweek feature will be the Midwinter Convention of the Florida Society of Ophthalmology and Otolaryngology, Jan. 20, to which all registrants are invited. The registrants and their wives may also attend the informal banquet at 8 p. m. Wednesday. The seminar schedule permits ample time for recreation. Lecturers on ophthalmology will be Drs. William B. Anderson, Durham, N. C., William P. Beetham, Boston, William C. Owens, Baltimore, Algernon B. Reese and Maynard C. Wheeler, New York; lecturers in otolaryngology, Drs. Edwin N. Broyles, Baltimore, Howard P. House, Los Angeles, William J. McNally, Montreal, Canada, Dorothy Wolff, Ph.D., and Dr. Degroff Woodman, New York.

ILLINOIS

Fellowships in Statistics.—Three $4,000 postdoctoral fellowships in statistics are offered for 1954-1955 by the University of Chicago to holders of the doctor's degree or its equivalent in research accomplishment. The purpose of these fellowships is to acquaint established research workers in the biological, physical, and social sciences with the role of modern statistical analysis in the planning of experiments and other investigative programs and in evaluation of empirical data. The closing date for applications is Feb. 15, 1954; instructions for applying may be obtained from the Committee on Statistics, University of Chicago, Chicago 37.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health. Programs should be received at least three weeks before the date of meeting.

Chicago

Dr. White to Lecture on Rheumatic Fever.—The first annual Harry G. Remer lecture on rheumatic fever will be delivered by Dr. Paul D. White, Boston, Dec. 11, 8 p. m., at La Rabida Sanitarium. This lecture is open to the public and is free.

Dr. Baker Appointed Professor of Urology.—Dr. Roger C. Baker Jr., associate professor of urology, University of Chicago School of Medicine and the Albert Merritt Billings Hospital, has been appointed professor of urology at the Georgetown University School of Medicine, Washington, D. C. Dr. Baker has engaged in work in urology also at the U. S. Naval Hospital in Philadelphia and the Massachusetts Memorial Hospitals in Boston. In 1950 he received the annual research award of the American Urological Association.

Medical Stamps.—At the annual exhibit of the Philatelic Society in Chicago, Dec. 3-5, Miss Margaret M. Bates, medical sciences librarian, University of Illinois, is exhibiting 54 pages of stamps depicting medical and scientific achievements from mythology and from Greek, Arabic, and Egyptian medicine and the subsequent primitive witch doctor, to the era of scientific specialization. Physicians who were statesmen, presidents of their countries, and explorers, others honored for their medical achievements, and cancer, leprosy, bacteriology, pathology, medicine, child welfare, and medical congresses are among the subjects.

Personal.—Dr. August F. Daro was elected chairman of the obstetric and gynecologic section of the International College of Surgeons at the annual meeting in New York.——Richard J. Winzler, Ph.D., professor and head of the department of biochemistry, University of Illinois College of Medicine, has been named consultant to the department of biochemistry of Cook County Hospital and the Hektoen Institute for Medical Research.——Dr. Ulysses G. Dailey, past president of the National Medical Association and former editor of its journal, has returned from a second tour of foreign countries under the auspices of the U. S. Department of State, as "leader-specialist" of the U. S. Information and Educational Service. Dr. Dailey delivered addresses at the All-Pakistan Medical Conference in Lahore, the India Medical College in Gwalior, the University of Ceylon, and numerous meetings of medical associations and special groups in Pakistan, India, Ceylon, and Africa.

IOWA

Society News.—Leslie M. FitzGerald, D.D.S., Dubuque, president-elect of the American Dental Association, was recently honored by the Dubuque County Medical Society at a banquet and program in the Hotel Julien, Dubuque. Officers of the American Dental Association and the Iowa State Dental Society were guests, together with the Dubuque County Dental Society and many dentists from Iowa, Illinois, and Wisconsin.

MICHIGAN

Lecture on Arthritis.—The Wayne County Medical Society, Detroit, will have as its speaker, Dec. 7, Dr. Otto Steinbrocker, New York, who will discuss "Treatment of Arthritis."

Edsel B. Ford Lecture.—On Dec. 8, at 8:15 p. m. in Henry Ford Hospital auditorium, James Hillier, Ph.D., research physicist, R.C.A. Laboratories, Princeton, N. J., will present the Edsel B. Ford lecture, "Some Results of the Application of Electron-Microscopy to Medicine."

Medicolegal Institute.—This institute, under the sponsorship of the State Bar of Michigan, will be held at the Sheraton-Cadillac Hotel, Detroit, Dec. 10-11. This will be the first "integral short course" of an over-all "three interval course," each to follow at an approximate six month period. Members of the Michigan State Medical Society are cordially invited. Advance registrations may be made by sending $25, payable to the Michigan Law Institute, % State Bar of Michigan, 412 Olds Tower Bldg., Lansing.

MISSOURI

Lecture on Gout.—Dr. Alexander B. Gutman, professor of medicine, Columbia University College of Physicians and Surgeons, New York, will speak in the Auditorium of Kansas City Municipal Hospital No. 1 on Dec. 17 at 8 p. m. His subject will be "Gout."

Society News.—The St. Louis Society of Neurology and Psychiatry will have as guest speaker on Dec. 10 at 8:15 p. m. Dr. Henry A. Davidson of the Veterans Administration Central Office, Washington, D. C., who will present "Role of the Psychiatrist in the Administration of Criminal Justice." Discussion will be by Dr. Val B. Satterfield of St. Louis. The meeting will be held in Elliott Auditorium of McMillan Hospital, St. Louis.

Personal.—Dr. Julius Jensen, St. Louis, has received the Distinguished Service award given annually by the American Medical Writers' Association to a member of the association, "who has made distinguished contributions to medical literature or rendered unusual and distinguished service to the medical profession." Dr. Jensen is president-elect of the Missouri Heart Association, a former professor at Washington University School of Medicine, and the author of books and scientific articles.

NEW JERSEY

Joint Meeting for Martland Lecture.—The Essex County Pathological and Anatomical Society will meet with the Academy of Medicine of New Jersey and the Essex County Medical Society, Dec. 9, 9 p. m., at the Academy of Medicine, 91 Lincoln Park, Newark, to hear Dr. Paul Klemperer, pathologist to Mount Sinai Hospital and professor of pathology, Columbia University College of Physicians and Surgeons, New York, deliver the Harrison S. Martland lecture. A dinner will precede the meeting.

Tumor Slide Seminar.—The New Jersey Society of Clinical Pathologists will hold its annual slide seminar on unusual tumors at the Nurses' Auditorium of Presbyterian Hospital, Newark, Dec. 12, 2 p. m. Drs. Fred W. Stewart and Frank W. Foote Jr. of the Memorial Center for Cancer and Allied Diseases, New York, will act as moderators. Slides and case histories prepared by the Bureau of Pathology, New Jersey State Department of Health, are being sent to all members of the state society of pathologists. Voting on the slides will be analyzed by Drs. Stewart and Foote at the meeting. Visitors to the seminar will be welcome.

General Practitioners Meet in Newark.—The New Jersey Academy of General Practice will hold its annual scientific session Dec. 9 at the Hotel Essex House, Newark. "Office Diagnosis and Treatment of Upper Gastrointestinal Disturbances" will be developed in the following program:

Moses Paulson, Baltimore, Practical Consideration of Functional Disorders of the Stomach.
Eddy D. Palmer, Washington, D. C., Specific and Nonspecific Gastric Inflammation, Using Office Methods for Diagnosis.
Emmanuel Deutsch, Boston, Gastric Cancer.
Sara M. Jordan, Boston, Treatment of Peptic Ulcer with Special Emphasis on the Use of the Newer Drugs.

All physicians are invited. There is no registration fee.

NEW YORK

Hospital News.—The Jewish Sanitarium and Hospital for Chronic Diseases, Brooklyn, will present "Urologic Complications in Gynecology" by Dr. Houston S. Everett, associate professor of gynecology, Johns Hopkins University School of Medicine, Baltimore, Dec. 10, 8:30 p. m., in the auditorium. Dr. Everett is the author of "Gynecological and Obstetrical Urology." Medical guests are cordially invited.

Meeting on Circulatory Diseases.—The New York Society for Circulatory Diseases will devote its regular meeting, 8:30 p. m., Dec. 8, in the New York Academy of Medicine building, to consideration of treatment of acute cardiac emergencies in myocardial infarction. Dr. Maurice L. Tainter, director, Sterling-Winthrop Research Institute, Rensselaer, will speak on shock, and Dr. Herbert J. Kayden, clinical instructor in medicine, New York University College of Medicine, will discuss "Paroxysmal Arrhythmias and Heart Block."

Appointments at Brookhaven Laboratory.—Recent appointments to the medical department of Brookhaven National Laboratory, Upton, include: Drs. George C. Cotzias and Bernard G. Stall III, each formerly assistant to the institute and assistant to the hospital at the Rockefeller Institute for Medical Research, New York; Dr. Charles G. Lewallen, Cleveland, formerly at the U. S. Naval Hospital, St. Albans; Dr. Edward T. Dunham; Dr. Laurence S. Maynard, Riverhead, N. Y., previously deputy commissioner of the Suffolk County Department of Health; and Dr. Hadley L. Conn Jr., Philadelphia.

Pilot Rehabilitation Project.—The diagnostic and evaluation division of the Queens Rehabilitation Program, a pilot project for handicapped children for other communities of the nation, was dedicated on Nov. 10 at Queens General Hospital, 164th St. and Grand Central Parkway, Jamaica. The division's rehabilitation program grew out of two years' planning by representatives of 20 health, welfare, civic, and business groups working with the Association for the Aid of Crippled Children. The program will seek out all Queens children who need help, correct the handicapping condition as far as possible, help the children to develop healthy attitudes, promote a better understanding of the handicapped, provide training opportunities, and stimulate research in methods of prevention, early discovery, and proper care of handicapping conditions.

Buffalo Dedicates Capen Hall.—The University of Buffalo schools of medicine and dentistry on Dec. 11-12 will dedicate Samuel P. Capen Hall, a building recently completed at a cost of $4,500,000 and named for the chancellor emeritus of the university, who will be guest of honor. Friday morning the following symposium will be presented:

The University and the Community, J. Roscoe Miller, Northwestern University, Evanston, Ill.
The Heritage of William Osler in 1953, Stanley E. Dorst, University of Cincinnati College of Medicine.
Trends in Dental Education, Maynard K. Hine, D.D.S., Indiana University School of Dentistry, Indianapolis.
The Cornerstone: Samuel P. Capen, Mr. John M. Russell, New York, John and Mary R. Markle Foundation.

Friday afternoon Dr. Stockton Kimball, dean, University of Buffalo School of Medicine, will preside at a conference on structural and immunological basis of biological specificity, during which Dr. Ernest Witebsky, professor of bacteriology and immunology, will discuss "Immunological Aspects of Biological Specificity." Robin R. A. Coombs, Ph.D., assistant director of research, department of pathology, University of Cambridge, England, will present "Immunology and the Natural Sciences." At 9:30 a. m. Saturday, Dr. Charles H. Best, director, Banting-Best Institute, University of Toronto, Canada, will preside at the following medical conference:

Fat in Parenteral Nutrition, Fredrick J. Stare, Harvard School of Public Health, Boston.
Amino Acids in Parenteral Nutrition, Herbert Pollack, Columbia University College of Physicians and Surgeons, New York.
Parameters of Electrolyte Needs During Parenteral Nutrition, Thaddeus S. Danowski, University of Pittsburgh School of Medicine.
Metabolic Consequences of Stress in Man, Jerome W. Conn, University of Michigan Medical School, Ann Arbor.
The Diet and the Cholesterol Problem, Ancel B. Keys, Ph.D., University of Minnesota Medical School, Minneapolis.

During the dental conference, which will be held simultaneously, Dr. William F. Harrigan, New York University College of Dentistry, will consider "Diagnosis in the Field of Oral Surgery." At the general alumni luncheon in the Clark Memorial Gymnasium, 12:30 p. m., Dr. Charles Gordon Heyd, New York, past president of the American Medical Association, will discuss "The Place of a Private University in Our Society." On Sunday the hall will be open to the public from 2 to 6 p. m.

New York City

Dr. Lewis to Head Neuropsychiatric Institute.—Dr. Nolan D. C. Lewis, director of the New York State Psychiatric Institute since June, 1936, has retired from that position to devote full time to his new work as director of research in neurology and psychiatry of New Jersey hospitals and agencies. His headquarters are at the Neuropsychiatric Institute, Skillman, N. J., formerly known as the State Village for Epileptics. He will continue his work as managing editor of the *Journal of Nervous and Mental Disease*, the *Psychoanalytic Quarterly*, and the *Journal of Child Behavior*.

Courses in Accident Prevention.—The Center for Safety Education, New York University, will offer courses in industrial and traffic accident prevention during the spring term, which begins Feb. 1, 1954. Courses will include: Safety Directors and Safety Engineers—Their Qualifications, Duties, and Responsibilities; Safety Organization: Values and Limitations; Management and Supervision in Accident Prevention; Industrial Hygiene and Occupational Diseases; Accident Prevention for Operators of Smaller Motor-Vehicle Fleets: Operating the Program; Special Problems in Accident Prevention; Psychology of Accident Prevention; Accident Prevention for Small Firms; and Marine Accident Prevention. Information may be secured from the Center for Safety Education, New York University, Washington Square, New York 3.

Assembly in Anesthesiology.—The New York State Society of Anesthesiologists will hold its seventh postgraduate assembly in anesthesiology, Hotel New Yorker, Dec. 9-12. Topics for discussion include the neuromuscular junction, hospital hazards, artificial support of circulation, adrenal mechanisms pertinent to anesthesiology, physiology and pharmacology of hypotension, applied pharmacology and mechanisms of action of barbiturates, local anesthesia, and neonatal survival. "Lunch with the Experts," round-table discussions, will be held Thursday and Friday. Saturday will be devoted to a residents' program. There will be a dinner dance Thursday, and Friday Dr. Louis H. Bauer, Hempstead, Immediate Past President of the American Medical Association, will be guest speaker at dinner. He will present "Current Medical Problems Affecting the Anesthesiologists."

Leukemia Award.—The Robert Roesler de Villiers award was conferred on Dr. Ludwik Gross, Oct. 20, for his contributions to the knowledge of the nature and cause of leukemia. The award was presented at ceremonies at the New York Academy of Medicine, in which Dr. Maxwell M. Wintrobe, University of Utah School of Medicine, Salt Lake City, and Dr. William B. Castle, Harvard Medical School, Boston, spoke about leukemia research. Dr. Gross, who is chief of research at the Veterans Administration Hospital, New York, was associated with the Pasteur Institute in Paris for seven years and received the Chevillon prize of the Academy of Medicine in Paris in 1937. The Robert Roesler de Villiers Foundation was created in 1949 in memory of a youth who died of leukemia. Through periodic international contests the foundation offers awards to researchers all over the world for development toward the prevention, effective treatment, or cure of leukemia. Members of the jury, in addition to Drs. Wintrobe and Castle, are Dr. Albert Alder, University of Zurich, Switzerland, and Dr. Jan Waldenstroem, University of Lund, Malmoe, Sweden. In this, the second contest, 226 papers were submitted from 22 countries in six languages. The foundation will support, financially or otherwise, studies of theories or therapies which the jury considers of potential value. It also will assist needy leukemia patients. The foundation is not endowed and depends entirely on voluntary contributions, which are tax exempt.

Personal.—Dr. Samuel Rosen, associate otologist at the Mount Sinai Hospital, has gone to Tel Aviv at the invitation of the Israeli government to work in the new audiology center and to teach surgical treatment of Ménière's disease and otosclerosis.——Dr. Jerome L. Leon, former supervisor of Riverside Hospital's narcotics treatment division, has been named medical director and superintendent of the Sanatorium of the Jewish Consumptives' Relief Society at Spivak, Colo. He succeeds Dr. William S. Klein, who has taken a position with the Veterans Administration in Albuquerque, N. Mex.——Dr. Madison Baldwin Brown, member of the board of directors of the Hospital Council of Greater New York, has been appointed medical director of Hahnemann Hospital, Philadelphia, to succeed Dr. Raymond S. Leopold, retired. Dr. Brown has served as medical director of Roosevelt Hospital, assistant professor of hospital administration at Johns Hopkins Hospital, Baltimore, and as a staff member of Columbia University College of Physicians and Surgeons.——Dr. W. Lynwood Heaver has been appointed medical director of the National Hospital for Speech Disorders, 61 Irving Place.——Dr. Donald B. Armstrong, second vice-president of the Metropolitan Life Insurance Company, will retire as head of the health and welfare division on Dec. 31 and will be succeeded by Dr. William P. Shepard of the company's Pacific Coast head office in San Francisco, who recently was transferred to New York. Dr. Shepard has served on the A. M. A. Council on Industrial Health and as president of the American Public Health Association.

OHIO

Society News.—Dr. Hayes Martin, New York, will discuss "Diagnostic Significance of a Lump in the Neck" before the Fort Steuben Academy of Medicine, meeting in the Fort Steuben Hotel, Steubenville, Dec. 8. Physicians, interns, and graduate nurses are invited. Information may be obtained from Dr. Edward B. Weinman, secretary-treasurer, National Exchange Bank Building, Steubenville.

Cancer Laboratory to Memorialize Senator Taft.—Judge Alfred K. Nippert, formerly of the Hamilton County Court of Common Pleas, has announced a gift of $100,000 toward the creation of a cancer research laboratory in memory of the late Sen. Robert A. Taft as part of the Christ Hospital Institute of Medical Research, Cincinnati. Judge Nippert, chairman of the board of Christ Hospital, last year gave $400,000 toward erection of the new medical research building at this hospital.

PENNSYLVANIA

Society News.—On Dec. 15 the Allegheny County Medical Society, 225 Jenkins Bldg., Pittsburgh, will hold a joint meeting with the Western Pennsylvania Heart Association. Dr. Wright R. Adams, professor of medicine, University of Chicago School of Medicine, will discuss "Pulmonary Hypertension."

Appoint Director of Child Guidance Center.—Dr. William F. Finzer, director of the Guidance Institute of Berks County at Reading for the past five years, has been named director of the Pittsburgh Child Guidance Center at the University of Pittsburgh Medical Center. He will also be an assistant professor of psychiatry in child development at the University of Pittsburgh School of Medicine. Dr. Finzer practiced psychiatry at the Menninger Clinic, Topeka, Kan., 1944-1945 and then for two years was with the U. S. Army, serving as chief of neuropsychiatric service for the Neuropsychiatric Center in Tokyo.

Philadelphia

Dr. Gruber Goes to California.—Dr. Charles M. Gruber, professor of pharmacology, Jefferson Medical College of Philadelphia since 1932, has been named head of the department of pharmacology at the College of Medical Evangelists, Loma Linda, Calif. Dr. Gruber is a past president of the American Society for Experimental Biology and Medicine.

TEXAS

Medical Students' Day in Galveston and Houston.—The Texas Medical Association and the local medical societies will sponsor in Houston and Galveston identical programs, designed to acquaint medical students with the practical aspects of future medical practice. In Houston, the meeting will begin at 4 p. m. on Dec. 11 in the Baylor University College of Medicine auditorium with greetings by Dr. John K. Glen, Houston, president of the Harris County Medical Society. In Galveston, the University of Texas Medical Branch will begin its program at 9:30 a. m. on Dec. 12 in the school auditorium, with greetings by Dr. Jesse B. Johnson Sr., president of the Galveston County Medical Society. On each program will be an address to senior students by Dr. George Turner, El Paso, president of the Texas Medical Association, whose subject will be "Your Responsibility as Doctors." The speakers' panel includes: "Your Practice and Public Opinion" by Dr. Troy A. Shafer, Harlingen, chairman, committee on public relations, Texas Medical Association; "You and the Medical Society" by Dr. Francis J. L. Blasingame, Wharton, member of the A. M. A. Board of Trustees; "The Legal Aspects of Your Practice" by Philip R. Overton, Austin, general counsel of the Texas Medical Association; and "The Business Side of Your Practice" by Dr. Harvey Renger, Hallettsville, chairman, council on medical economics, Texas Medical Association.

WISCONSIN

State Medical Election.—At the recent annual meeting in Milwaukee, the State Medical Society of Wisconsin chose the following new officers: president, Dr. H. Kent Tenney, Madison; president-elect, Dr. Arthur J. McCarey, Green Bay; speaker of the House of Delegates, Dr. Lien O. Simenstad, Osceola; and alternate delegate to the A. M. A., Dr. George E. Forkin, Manasha.

New Paging System.—A new system for public paging of its members has been activated by the Medical Society of Milwaukee County. Each member has been assigned a numbered card, the number to be used by members of his family, his hospital, the Medical Society Physicians' Service, or his office when it is necessary to reach him while he is in a public place or at a public gathering.

Sparta Honors Dr. Beebe.—Residents of Sparta and the surrounding area recently gathered at the courthouse square to pay tribute to Dr. Spencer D. Beebe, who in 1954 will complete 50 years of service to the community. "Dr. Beebe Night" was sponsored by the Sparta Kiwanis Club. Dr. Beebe, a life member and past officer of the Wisconsin State Medical Society, was honored by the society as the Wisconsin country practitioner of 1950.

PUERTO RICO

Annual Meeting in Santurce.—The Puerto Rico Medical Association will hold its annual assembly in the association headquarters, Santurce, Dec. 9-13, under the presidency of Dr. Luis A. Sanjurjo, Santurce. Dr. Charles C. Higgins, Cleveland, will participate Thursday in a symposium on the management of urinary lithiasis. On Saturday there will be a symposium on current research in the basic medical sciences of the School of Medicine. Dr. Rudolph H. Kampmeier, Nashville, who with Dr. Felix M. Reyes, Santurce, will conduct a clinical pathological conference at the Hospital San Patricio on Friday, will discuss "The Variability of Diffuse Arteritis (Collagen Diseases)" on Saturday. Other guests of honor and their first presentations include:

Leo H. Bartemeier, Detroit, Utilization of Psychiatric Principles in the Practice of Medicine.
Vicente Pardo-Castello, Havana, Cuba, Early Diagnosis of Leprosy.
Frederick F. Yonkman, Summit, N. J., Certain Phases of the Modern Medical Treatment of Hypertension.
Joseph C. Yaskin, Philadelphia, Evaluation of Headache from the Standpoint of Diagnosis and Treatment.
George T. Pack, New York, Problems of Pigmented Moles and Malignant Melanoma.
Angel Jorge Echeverri, Santiago de Compostela, Spain, Anatomical Clinic Studies on Dysmorphogenesis of Sacrolumbar Region.

GENERAL

Association of Medical Colleges.—At the recent annual meeting in Atlantic City, the Association of American Medical Colleges broadened its membership base to include individuals and organizations with an interest in medical education. Institutional membership had been limited to accredited medical schools. Membership is now open to medical school faculty members and others professionally linked to medical schools for an annual fee of $10; sustaining membership, at $1,000 a year, may be held by interested organizations. The 65th annual meeting, scheduled for Oct. 17-20, 1954, French

Lick Springs Hotel, French Lick, Ind., will be preceded by the association's Teaching Institute on Pathology, Bacteriology, Immunology and Genetics, Oct. 10-15, and by a meeting of medical school cancer coordinators Oct. 15-16 (*J. A. M. A.* Nov. 14, 1953, p. 1023).

Meeting on Nervous and Mental Disease.—The Association for Research in Nervous and Mental Disease will hold its annual meeting at the Hotel Roosevelt, New York, Dec. 11-12. The chief topics for discussion are "Genetics, Human Inheritance and Environmental Effects" and "Neurological and Mental Patterns and Their Inheritance." Participants in the program include Drs. Albert B. Sabin and Josef Warkany, Cincinnati; Arnold L. Gesell and Milton J. E. Senn, New Haven, Conn.; Tryphena Humphrey, Pittsburgh; C. Nash Herndon, Winston-Salem, N. C.; George A. Jervis, Thiells, N. Y.; F. H. Tyler, Salt Lake City; John W. Schut, Anoka, Minn.; William G. Lennox, Boston; Donald H. Jolly, Wrentham, Mass.; Harold G. Wolff, Bernard D. Davis, and Franz J. Kallmann, New York; Leo Kanner, Baltimore; Robert E. Yoss, and James V. Neel, Ann Arbor, Mich.

Borden Award in Nutrition.—Nominations are solicited for the 1953 award of $1,000 and a gold medal made available by the Borden Company Foundation. The American Institute of Nutrition will make this award in recognition of distinctive research by investigators in the United States and Canada that has emphasized the nutritive significance of the components of milk or of dairy products. The award may be divided between two or more investigators, but employees of the Borden Company are not eligible for the award. Formal presentations will be made at the annual meeting of the institute in the spring of 1954. Nominations, which must be in the hands of the chairman of the nominating committee, J. B. Brown, Ph.D., Institute of Nutrition and Food Technology, Ohio State University, Columbus 10, Ohio, by Jan. 1, 1954, should be accompanied by such data relative to the nominee and his research as will facilitate consideration for the award.

Damon Runyon Cancer Grants.—The Damon Runyon Memorial Fund for Cancer Research allocated $76,500 for the month of October for seven institutional grants and two fellowships to train cancer research investigators. The grants included: $10,000 for a project entitled "The Relationship of Hormones in Neoplasia," to be conducted by Dr. Albert Segaloff at Tulane University of Louisiana Medical School, New Orleans; $20,000 to the Institute for Cancer Research, Inc., Philadelphia, for a projected research study under Dr. Stanley P. Reimann, entitled "Physicochemical Study of Cancer Patients"; and $10,000 to Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota Medical School, Minneapolis, who heads an investigation on endocrine aspects of malignant growth. To date of report, $7,323,286 had been allocated by the fund in 395 grants and 258 fellowships, in 170 institutions in 47 states, the District of Columbia, and 14 foreign countries.

Booklet for Multiple Sclerosis Patients.—An illustrated booklet "Mental Health and MS," published by the National Multiple Sclerosis Society, 270 Park Ave., New York 17, is available to multiple sclerosis patients, according to an announcement by Dr. Harold R. Wainerdi, New York, medical director of the society. The booklet is the result of a grant made in 1949 by the society to the New York University-Bellevue Medical Center to support a study on the psychological factors in multiple sclerosis, under the direction of Molly Harrower, Ph.D., who is now consultant in psychology, U. S. Army, and research director, Court Intake Project, New York City, Court of Domestic Relations. The booklet contains two vocational interest tests designed to give patients an understanding of their interests and vocational potentialities. The importance of hobbies and creative interests is stressed. The booklet will be distributed without charge to multiple sclerosis patients on request directed to the National Multiple Sclerosis Society or any affiliated chapter of the society. A second mental health booklet by the same author, for use of physicians who treat multiple sclerosis patients, will be published shortly.

Radiologists Meet in Chicago.—The Radiological Society o
North America will hold its annual meeting, Dec. 13-18, a
the Palmer House, Chicago. Fifty-seven papers are schedule
for presentation, and seven will be read by title. Ninety-two
speakers by invitation are listed. A symposium on isotope
studies is scheduled for Monday morning. Monday afternoo
a chest survey will include "The Value of Chest Surveys fro
the Standpoint of the Internist," "The Radiologist and Ches
Surveys," "The Administrator Looks at Chest Surveys," "Ches
Surveys as Used by the Chest Physician," and "What th
Public Thinks of Chest Surveys." The radiobiology sessio
will be held Tuesday morning, the radiological physics sessio
Wednesday morning, and the radiobiology and physics sessio
Friday morning. Thursday morning there will be a panel di
cussion on low back pain and a symposium on radiation uni
and Thursday afternoon, a symposium on rotation therap
The annual banquet will be held Thursday, 7 p. m. Th
Carman lecture, "Observations in Atomic Medicine," by D
Roger Allen Harvey, acting dean, University of Illinois Colle
of Medicine, Chicago, will be delivered Tuesday at 8:30 p.
The society has scheduled 47 refresher courses.

International Cancer Congress.—Physicians are invited to pr
sent papers at the sixth International Cancer Congress, to
held in São Paulo, Brazil, July 23-29, 1954, under the sponso
ship of the International Union Against Cancer. The progra
will include sections on fundamental cancer research, clinic
studies on cancer, and cancer control. Registration blanks a
available from the Chairman, National Committee on Int
national Union Against Cancer, National Research Counc
2101 Constitution Ave. N.W., Washington 25, D. C. Fi
copies of an abstract of each paper proposed for presentati
must be sent to the chairman by Jan. 15, 1954. Abstracts a
not to exceed 250 words and must be accompanied by a ti
and the name, address, academic or professional title, a
institutional affiliation of the investigator or physician. Th
requirements do not apply to persons who have been invit
to participate by the president of the congress unless appli
tion is made for travel allotments as described below. It
expected that round-trip transportation by air from Miami
São Paulo will be available for about $480. Detailed inform
tion regarding travel arrangements and hotel reservations m
be obtained from Dr. Brewster S. Miller, American Can
Society, Inc., 47 Beaver St., New York 4. Travel allotme
of approximately $600 each will be available to a limit
number of individuals requiring such assistance. Applicatio
for travel allotments must be submitted in quintuplet to
chairman by Jan. 15. They should be in letter form, givi
information concerning age, training, publications in cancer
related fields, and academic or professional status. Applica
not planning to present papers should include five copies
abstracts, as described above, of major current investigati
work. A letter from the laboratory director, or appropri
administrative officer, approving the application is a
necessary.

Society News.—At the annual meeting of the **National Gas
enterological Association** in Los Angeles Dr. Sigurd W. Joh
sen, Passaic, N. J., assumed the presidency; Dr. Lynn
Ferguson, Grand Rapids, Mich., was named president-ele
and Drs. James T. Nix, New Orleans, Arthur A. Kirch
Los Angeles, C. Wilmer Wirts, Philadelphia, and Frank
Borrelli, New York, were chosen as vice-presidents. Reelect
were Dr. A. Xerxes Rossien, Kew Gardens, N. Y., secreta
Dr. Roy Upham, New York, secretary-general, and Dr. Eli
Katz, New York, treasurer. Dr. Samuel Weiss, New York, w
renamed as editor-in-chief of *The Review of Gastroenterolo*
The 19th annual convention of the association will be held
Washington, D. C., in October, 1954.——At the annual me
ing in Chicago the **College of American Pathologists** elect
the following new governors: Drs. Cyrus C. Erickso
Memphis; John J. Clemmer, Albany, N. Y.; Donald A. Nicke
son, Salem, Mass.; James W. Kernohan, Rochester, Min
and Allen R. Moritz, Cleveland.——At the annual meeti
in Nashville the **National Medical Association** installed D
A. Porter Davis, Kansas City, Kan., as president and nam
Dr. Matthew Walker, Nashville, president-elect; Drs. John
Thornton, Little Rock, Ark., Evan A. Gilkes, Baltimore, a

George B. Lennox, Omaha, vice-presidents, and Dr. Eugene T. Taylor, St. Louis, treasurer.——At the annual business session in Chicago the **American Association of Blood Banks** elected the following officers: president, Dr. Aaron Kellner, New York; vice-president, Dr. John R. Upton, San Francisco; president-elect, Dr. Merlin L. Trumbull, Memphis, Tenn. Named as district directors were Dr. Peter Vogel, New York, Dr. Coye C. Mason, Chicago, Dr. John H. Carlquist, Salt Lake City, and Dr. William C. Levin, Galveston, Texas. Re-elected for treasurer and secretary respectively were Mrs. Bernice Hemphill, San Francisco, and Miss Marjorie Saunders, Dallas, Texas. The 1954 meeting is scheduled for Sept. 13-15 at the Shoreham Hotel, Washington, D. C.——The **North Pacific Surgical Association** held its 40th annual meeting Nov. 20-21 in Victoria, B. C., under the presidency of Dr. Thomas M. Jones of Victoria, B. C. Presentations included "Use of Radioactive Isotopes in Surgery," "Present Status of Vascular Grafts," "Further Studies on the Billroth I Operation for Peptic Ulcer," and "Importance of a Short Afferent Loop in Gastrectomy for Peptic Ulcer: a Study of the Protective Mechanisms Involved."——At the annual meeting in Kansas City, Mo., the **Mid-Continent Psychiatric Association** elected the following officers: president, Dr. Clarence J. Kurth, Wichita, Kan.; vice-president and president-elect, Dr. Paul S. Hines, Kansas City, Mo.; secretary-treasurer, Dr. Frank F. Merker, Topeka, Kan.; councilors, Drs. Robert G. Carnahan, Little Rock, Ark., William Rottersman, Topeka, Kan., G. Wilse Robinson Jr., Kansas City, Mo., and Harold G. Sleeper, Oklahoma City.——At the annual meeting in Minneapolis the **Mississippi Valley Trudeau Society** elected the following officers: president, Dr. Ralph I. Canuteson, Lawrence, Kan.; president-elect, Dr. Ejvind P. Fenger, Minneapolis; vice-president, Dr. Leon J. Galinsky, Des Moines, Iowa; and secretary-treasurer, Dr. Jesse A. Stocker, Springfield, Ill. William H. Feldman, D.V.M., Rochester, Minn., was awarded the Dearholt medal for outstanding work done in the development of streptomycin as a chemotherapeutic agent in the treatment of tuberculosis.——At the annual meeting in Chicago the **American Society for the Study of Arteriosclerosis** elected the following officers: president, Dr. Russell L. Holman, New Orleans; vice-president, Dr. Louis N. Katz, Chicago; and secretary-treasurer, Dr. O. J. Pollak, Dover, Del.——At a recent meeting of the **Baltimore-Washington Dermatological Society** the following officers were elected for a term of one year: chairman, Dr. Israel Zeligman, Baltimore; vice-chairman, Dr. Jack L. Derzavis, Washington, D. C.; and secretary-treasurer, Dr. Raymond C. V. Robinson, Baltimore.——The **New England Society of Anesthesiologists** met on Dec. 4 at the submarine base, New London, Conn., for the following program:

Decompression Sickness, Commander Gerald J. Duffner, Washington, D. C.
Explanatory Talk with Slides on Submarine Escape Training.
Demonstration of Submarine Escape Training Tank.
Underwater Respiratory Apparatus, Lieut. P. P. Newman.
Oxygen Poisoning, Commander Jack L. Kinsey.
Carbon Dioxide Toxicity and Oxygen Requirements, Karl E. Schaeffer.

LATIN AMERICA

Medical Meeting of French-Speaking Countries.—The third Medical Congress of French-Speaking Countries in the Caribbean will meet jointly with the Haitian Chapter of the International College of Surgeons, Dec. 15-21, at Port-au-Prince, Haiti. For information write Dr. Constant Pierre-Louis, School of Medicine, Port-au-Prince, Haiti.

FOREIGN

Prize for Medicosurgical Films.—The annual prize for medicosurgical cinema of 100,000 francs (about $290) and other awards will be given during the last session of the course on "Actualités médico-chirurgicales" at the Faculté de Médecine de Paris in March, 1954. The prizes are offered only for amateurs' films, unpublished, not subsidized, and not produced by any laboratory or firm. Films may be silent or sound, in black and white, or in color but must be 16 mm. Films must reach La Presse Médicale, 120, Boulevard Saint-Germain, Paris VIe, before March 8, 1954.

MEETINGS

AMERICAN MEDICAL ASSOCIATION: Dr. George F. Lull, 535 North Dearborn St., Chicago 10, Secretary.

1954 Annual Meeting, San Francisco, June 21-25.

1954 Clinical Meeting, Miami, Florida, Nov. 30-Dec. 3.

1955 Annual Meeting, Atlantic City, N. J., June 6-10.

1955 Clinical Meeting, Boston, Nov. 29-Dec. 2.

American Academy of Dermatology and Syphilology, Palmer House, Chicago, Dec. 5-10. Dr. John E. Rauschkolb, P. O. Box 6565, Cleveland 1, Secretary.

American Academy of Obstetrics and Gynecology, Netherland Plaza Hotel, Cincinnati, Dec. 14-16. Dr. C. Paul Hodgkinson, 116 South Michigan Blvd., Chicago 3, Secretary.

American Federation for Clinical Research:

- Eastern Section, Amphitheater, Children's Medical Center, Boston, Jan. 4. Dr. Walter Judson, Evans Memorial Hospital, Boston, Chairman.
- Southern Section, Jung Hotel, New Orleans, Jan. 29. Dr. William Parson, University of Virginia School of Medicine, Charlottesville, Va., Chairman.
- Western Section, Auditorium, University of Oregon Medical School, Portland, Ore., Jan. 28. Dr. I. S. Edelman, University of California Medical Center, San Francisco Hospital, San Francisco 15, Secretary.

American Laryngological, Rhinological and Otological Society:

- Eastern Section, Waldorf-Astoria, New York, Jan. 8. Dr. Francis W. Davison, Danville, Pa., Chairman.
- Middle Section, Park Plaza Hotel, St. Louis, Jan. 18. Dr. Ralph J. McQuiston, 20 North Meridian St., Indianapolis 4, Chairman.
- Southern Section, Brown Hotel, Louisville, Ky., Jan. 16. Dr. Lester A. Brown, 490 Peachtree St., N.E., Atlanta 3, Ga., Chairman.

American Society for Surgery of the Hand, Palmer House, Chicago, Jan. 22. Dr. George V. Webster, 960 East Green St., Pasadena 1, Calif., Secretary.

Association for Research in Nervous and Mental Diseases, Hotel Roosevelt, New York, Dec. 11-12. Dr. Clarence C. Hare, 710 West 168th St., New York 32, Secretary.

Northwest Society for Clinical Research, Portland, Ore., Jan. 28. Dr. Arthur L. Rogers, 1216 S.W. Yamhill St., Portland, Ore., Secretary.

Radiological Society of North America, Palmer House, Chicago, Dec. 13-18. Dr. Donald S. Childs, 713 East Genesee St., Syracuse 2, N. Y., Secretary.

Regional Meetings, American College of Physicians:

- Eastern Pennsylvania, Philadelphia, Jan. 15. Dr. Thomas M. McMillan, 330 S. Ninth St., Philadelphia 7, Governor.

Southern Surgical Association, The Homestead, Hot Springs, Va., Dec. 8-10. Dr. John C. Burch, 2112 West End Ave., Nashville 5, Tenn., Secretary.

Western Society for Clinical Research, Portland, Ore., Jan. 29-30. Dr. Herbert N. Hultgren, Stanford Hospital, San Francisco 15, Secretary.

FOREIGN

Association of Surgeons of Great Britain and Ireland, Leeds, England, May 13-15, 1954. Dr. Henry W. S. Wright, 45 Lincoln's Inn Fields, London W.C.2, England, Honorary Secretary.

British Medical Association, Glasgow, Scotland, July 1-9, 1954. Dr. A. Macrae, B.M.A. House, Tavistock Square, London, W.C.1, England, Secretary.

Canadian Medical Association, Vancouver, B. C., Canada, June 18-22, 1954. Dr. T. C. Routley, 135 St. Clair Ave. W., Toronto 5, Ont., Canada, General Secretary.

Conference of International Union Against Tuberculosis, Madrid, Spain, Sept. 26-Oct. 2, 1954. Secretariat, Escuela de Tisiologia, Ciudad Universitaria, Madrid, Spain.

Congress of International Association for the Prevention of Blindness, New York, N. Y., U. S. A., Sept. 12-17, 1954. Professor Franceschetti, 2 Avenue Mirmot, Geneva, Switzerland, Secretary-General.

Congress of International Society of Surgery, Paris, France, May 21-22, 1954. Dr. L. Dejardin, 141, rue Belliard, Brussels, Belgium, General Secretary.

French Medical Congress of French Speaking Countries in the Caribbean, Port-au-Prince, Haiti, Dec. 15-21. For information write: Dr. Constant Pierre-Louis, School of Medicine, Port-au-Prince, Haiti.

Health Congress of the Royal Sanitary Institute, Scarborough, England, April 27-30. Mr. P. Arthur Wells, Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1, England, Secretary.

International Cancer Congress, Sao Paulo, Brazil, July 23-29, 1954. Prof. A. Prudente, 171 rua Benjamin Constante, Sao Paulo, Brazil, President.

International Conference on Thrombosis and Embolism, Basle, Switzerland, July 15-19, 1954. Dr. W. Merz, Chief Medical Officer, Gynecological Clinic, University of Basle, Basle, Switzerland, Hon. Secretary.

International Congress on Child Psychiatry, University of Toronto, Toronto, Ontario, Canada, Aug. 13-14, 1954. Miss Helen Speyer, International Association for Child Psychiatry, 1790 Broadway, New York 19, New York, U. S. A., Executive Officer.

International Congress of Clinical Pathology, Washington, D. C., U. S. A., Sept. 6-10, 1954. Dr. Robert A Moore, Washington University School of Medicine, St. Louis 10, Missouri, U. S. A., Chairman, Committee on Arrangements.

International Congress on Diseases of the Chest, Barcelona, Spain, Oct. 4-8, 1954 Mr. Murray Kornfeld, 112 East Chestnut St., Chicago 11, Illinois, Executive Secretary.

International Congress on Group Psychotherapy, Toronto, Ont., Canada, Aug. 12-14, 1954. Dr. J. L. Moreno, Room 327, 101 Park Ave., New York 17, N. Y., U. S. A., Director of Organizing Committee.

International Congress of Hematology, Paris, Sept. 6-11, 1954. Dr. Jean Bernard, 86 rue d'Assas, Paris 6^e, France, Secretary.

International Congress of the History of Medicine, Rome and Salerno, Italy, Sept. 13-20, 1954. For information write: Segreteria XIV Congresso Internazionale di Storia della Medicina, Instituto di Storia della Medicine, Citta Universitaria, Rome, Italy.

Williams, James Marcus, Warsaw, N. C.; University of Maryland School of Medicine, Baltimore, 1902; died July 30, aged 78, of coronary embolism.

DIED WHILE IN MILITARY SERVICE

Cocks, Charles Edward Jr. ⊕ Colonel, (MC), U. S. Army, San Francisco; born in San Francisco May 31, 1908; University of California Medical School, San Francisco, 1933; interned at the Highland Hospital of Alameda County and Peralta Hospital in Oakland; served as associate clinical professor of medico-military sciences and tactics at his alma mater; entered the medical reserve corps of the U. S. Army as a first lieutenant on May 13, 1933; served during World War II; became a lieutenant colonel on Dec. 2, 1943; entered the medical corps of the regular army as a major July 15, 1946; formerly chief of public health and welfare for the Armed Forces Far East Command; in June, 1951, received the master's degree and in 1952 the degree of doctor of public health, both in hospital administration, from the University of California School of Public Health; died in the Letterman Army Hospital Sept. 29, aged 45, of coronary occlusion and myocardial infarction.

Graveline, Ernest Louis Jr., Pawtucket, R. I.; born in Pawtucket, April 15, 1922; University of Nebraska College of Medicine, Omaha, 1949; interned at the White Plains (N. Y.) Hospital; certified by the National Board of Medical Examiners; entered the U. S. Army March 16, 1943, and was discharged Feb. 10, 1946; in May, 1949, was commissioned a first lieutenant in the Medical Corps, U. S. Army Reserve; in June, 1950, was promoted to captain; attached to the Third Battalion, 23rd Infantry Regiment, Second Division; captured by the communists in Korea on May 18, 1951; died as a prisoner of war in a communist prison camp Oct. 15, 1951, aged 29.

GOVERNMENT SERVICES

ATOMIC ENERGY COMMISSION

Fellowships in Industrial Medicine.—Eight fellowships in industrial medicine will be offered by the U. S. Atomic Energy Commission for the 1954-1955 academic year. The fellowship program, which was begun by the AEC four years ago, is designed to provide advanced training and on-the-job experience for physicians in the field of industrial medicine, particularly in relation to the atomic energy industry. The fellowships are open to U. S. citizens who hold M.D. degrees from approved medical schools and who have had at least one year of internship. In exceptional cases, equivalent experience may be accepted in lieu of the internship requirement. Successful candidates must be investigated by the FBI and approved by the AEC before receiving fellowships. Awards are for one year's academic training at institutions offering approved graduate courses in industrial medicine that provide special training facilities in the health problems associated with the atomic energy program. Normally, fellows will be eligible for a second, or in-plant, training year on successful completion of the academic year. In-plant training will be given in medical departments of major AEC plants and laboratories. There is a critical need for qualified industrial physicians in atomic energy installations, and at the end of the two year training period fellows may find employment in the program. There will be no commitment, however, on the part of the AEC to continue the applicant's training beyond the first year or to provide employment for him on the completion of training. Fellows will not be obligated to take the second year of training or to seek employment with the AEC or its contractors. The stipend during the first year is $3,600, with $350 additional for a wife and for each dependent child. Tuition and laboratory fees will be paid. The stipend for the second year is $6,000, with no additional amounts for a wife or children. The program is administered for the AEC by the Atomic Energy Project of the School of Medicine and Dentistry, University of Rochester, Rochester, N. Y. Fellows are selected by a committee headed by Dr. Robert A. Kehoe, director, Institute of Industrial Health, University of Cincinnati, and medical director, Ethyl Corporation. Applications for 1954-1955 fellowships should be submitted by Jan. 1, 1954, to AEC Fellowships in Industrial Medicine, Atomic Energy Project, University of Rochester, School of Medicine and Dentistry, Rochester, N. Y.

ARMY

Award of Legion of Merit.—Col. Henry C. Harrell, chief of the diagnostic section of the x-ray service at Brooke Army Hospital, has been awarded the Legion of Merit for distinguished work as radiological consultant to the Army Surgeon of the Far East command. He was cited for outstanding service as chief of the radiology service at Tokyo Army Hospital, for professional competence and devotion to duty in serving the sick and wounded, and for skill in interpretation of x-ray examinations. In addition to other duties, Colonel Harrell planned and directed a radiological survey of prisoners of war on Koje-do and prepared a valuable study on incidence of disease in the group. He is a member of the American College of Radiology and of the Radiological Society of North America.

Hospital News.—Dr. Jacob Finesinger, professor of psychiatry, University of Maryland School of Medicine, addressed officer-students of the military neuropsychiatry class at the Medical Field Service School, Ft. Sam Houston, Texas, recently during a two day visit to Brooke Army Medical Center. Dr. Finesinger lectured on goal-directed psychotherapy. He also conducted a program on the doctor-patient relationship at the Brooke Army Hospital monthly professional staff meeting.

VETERANS ADMINISTRATION

Residencies Available at Indianapolis.—Several residencies are available in internal medicine, pathology, and psychiatry at the Veterans Administration Hospital, Indianapolis. The hospital, located on the campus of Indiana University Medical Center, is affiliated with the medical center, and has programs integrated with it. These residencies are fully approved by the specialty boards. The stipends are as follows: junior resident (first year) $2,640 per annum, intermediate resident (second year) $2,970 per annum, and senior resident (third and fourth years) $3,300 per annum. In addition, Korean veterans may be eligible for assistance under the G.I. training benefits. Applications for residency training or information in this regard may be obtained from Dr. Matthew Winters, Chairman, Dean's Committee, Indiana University Medical Center, 1040 W. Michigan St., Indianapolis, Ind., or D. R. Robinson, M.D., Chief, Professional Services, VA Hospital, 1481 W. 10th St., Indianapolis, Ind.

Personal.—Dr. Joseph I. Fitzsimmons, chief of professional services at the VA Hospital in Omaha, Neb., has been named manager of the 250-bed VA Hospital at Iron Mountain, Mich. He succeeds Dr. Carleton Bates, who retired Oct. 24, 1953.

MISCELLANEOUS

Members of the Hoover Medical Task Force.—The announcement of 12 more appointments completes the membership of the Hoover Commission task force on medical services. Earlier the commission named Mr. Chauncey McCormick, Chicago businessman, as chairman, and Dr. Edwin L. Crosby, also of Chicago, as research director. The third appointment announced earlier was that of Dr. Walter Martin, President-Elect of the American Medical Association. The following have accepted appointment to the remaining posts:

Dr. Francis J Braceland, formerly dean, Loyola University School of Medicine, Chicago, now psychiatrist at Institute of Living, Hartford, Conn.

Dr. Edward Delos Churchill, chief of general surgical service, Massachusetts General Hospital, Boston.

Dr. Michael DeBakey, chairman of department of surgery, Baylor University College of Medicine, Houston, Texas.

Dr. Evarts A. Graham, surgeon-in-chief, Barnes Hospital and Children's Hospital, St. Louis.

Dr. Alan Gregg, vice-president of Rockefeller Foundation, New York.

Dr. Paul R. Hawley, U. S. Army, retired, Chicago, director, American College of Surgeons, former chief medical director, Veterans Administration.

Dr. Theodore George Klumpp, president, Winthrop-Stearns, Inc., New York.

Dr. Hugh Rodman Leavall, professor of public health practice, Harvard School of Public Health, Boston.

Dr. Basil C. McLean, professor of hospital administration, University of Rochester, New York.

Dr. James Roscoe Miller, president of Northwestern University, Chicago.

Dr. Milton C. Winternitz, chairman, division of medical sciences of National Research Council, New Haven, Conn.

Dr. Otto W. Brandhorst, dean of Washington University School of Dentistry, St. Louis.

The task force will study operations of all federal medical programs, including Veterans Administration and military, and will recommend possible consolidations. Officially the commission is known as the Commission on Organization of the Executive Branch of the Government. The first Hoover Commission proposed, among other medical changes, that all federal medical services be grouped under a United Medical Administration. The plan was defeated in Congress. The Hoover Commission medical task force has decided to do some of its work in Chicago but most of it in Washington. At its organization meeting, the force decided to meet in Washington every two weeks until the survey of federal medical programs has been completed.

BRAZIL

Total Gastrectomy.—Among the reasons for the increase of the survival time in recent reports on cancer of the body and cardial regions of the stomach as well as infiltrating tumors of the whole stomach, total gastrectomy is frequently referred to. While some distinguished surgeons in recent papers suggest the routine use of total gastrectomy for the treatment of all cases of cancer of the stomach, other practitioners, no less prominent, oppose this radical procedure. In a recent paper published in *Medicina-cirurgia-farmacia* (17:175, 1953), Dr. Fernando Paulino, head surgeon of the Rio de Janeiro Casa de Saude São Miguel, reports his personal experience in 20 cases in which total gastrectomy was performed in the four and a half years ended on Dec. 31, 1952, in this small and well-equipped hospital. All the 20 patients left the hospital in good general condition and tolerating well the prescribed diet. In all cases the malignancy of the lesions was ascertained by pathological examination. There were 16 men and 4 women, with the minimum age of 32 and the maximum of 72, the average age being 56. The resection involved, besides the stomach, the spleen in 16 cases, the lower third of the esophagus in 6, the pancreas in 3, the colon and the gallbladder in 2, and the adrenal in one. A solution of glucose, amino acids, and alcohol was used to administer fluids, proteins, and calories needed during the first three days after the operation. Oral feeding was used after the third day, which seems to improve the recuperation of the patients and has no ill effect on the healing of the anastomosis. In no case was a catheter used through the anastomosis. Of the 20 patients, 7 died of metastases within 10 months after the operation, 2 within 24 months, and one after 25 months. One patient was operated on eight months after the total gastrectomy, metastases having been then found involving the preaortic lymph nodes. This patient was not seen afterwards for follow-up. Among the nine patients still alive, one was still surviving two years and six months after the operation, one at one year and four months, and seven at less than 10 months.

Dr. Paulino says that his experience does not permit him to recommend total gastrectomy as routine treatment of early gastric carcinomas or of the pyloric region. These tumors should be treated by subtotal gastrectomy, with resection of the great and lesser omenta, four-fifths of the stomach, and 3 to 5 cm. of the duodenum. He thinks that total gastrectomy should be performed in cases of (1) carcinoma of the median part of the stomach; (2) carcinoma of the cardial region of the stomach; (3) carcinoma invading the whole stomach; (4) sarcoma of the stomach of any localization or histological type (such as leiomyosarcoma or lymphosarcoma). He points out that the indication for total gastrectomy in cases of nonmalignant lesions must be exceptional; polyposis gastrica seems to him the most legitimate case.

Spraying of Houses with DDT for Control of Leishmaniasis.—During the first trimester of 1947, Dr. F. Nery Guimarães, of the Rio de Janeiro Oswaldo Cruz Institute, studied an epidemic of mucocutaneous leishmaniasis in Suruí, a rural locality of the county of Magé, state of Rio de Janeiro, known as an endemic focus of the disease. Of 306 persons examined, 39 (12.7%) were found to have leishmaniasis on the basis of the presence of the parasite or the positivity of Montenegro's reaction. Also found were 24 persons with old scars suspected to be sequelae of leishmaniasis, this having been later confirmed by the intradermal test. In 12 houses, 136 sandflies (11.3 per house) were collected by hand, all of the species Phlebotomus intermedius; this species was also found, besides several sylvatic species, in the vicinity of the dwellings and the forest. Throughout the surveyed area, from the end of 1947 on, the Serviço Nacional de Malaria has sprayed all houses with chlorophenothane (DDT), at six month intervals. In 1953, after five years of this mosquito control work, at the same season the previous leishmania survey was performed, Dr. Guimarães and Dr. Fernando M. Bustamante, of the Servico de Malaria, carried out a new clinical and epidemiological investigation that will be described in a future issue of the *Revista Brasileira de Malariologia.* Following is a summary of their findings:

In a house to house canvass, only one (0.3%) of 296 persons in 74 dwellings was found to have leishmaniasis. Sandflies were searched for by hand in the interior of several houses, including the 12 from which numerous specimens had been captured during the first survey. The results were entirely negative. New captures were then performed, this time by means of spraying an insecticide with a pyrethrum basis (Flytox) through a manual pump. Ninety-four houses were inspected, all having been sprayed except 20 that were uninhabited or closed at the moment. These 94 houses represented almost all of the community. The spraying of each house, done at the first hours of the evening, lasted an average of 20 minutes, and, at the end, a careful search was made for the insects. No sandfly was found inside the dwellings. In the outside—near the living areas and in the forest—manual captures were made, and, as had occurred before the DDT spraying of the region, many sandflies were collected, a part of them Phlebotomus intermedius, i. e., the same species found before in the interior of the houses.

As ascertained by the authors, the leishmania case rate fell from 12.7% to 0.3% after the regular chlorophenothane spraying of the houses. Since about 50% of the persons infected with leishmaniasis found before the spraying were treated thereafter, this may have been a factor in limiting the normal spread of the disease, but this could never explain the almost total disappearance of the disease, which is undoubtedly the result of the absence of sandflies in the dwellings. On the other hand, as these insects are still found outdoors, the extradomiciliary transmission of the disease should have had only a secondary role in the increase of the intensity of the focus. This means that the disease was, at the time of the former investigation in this area, spread predominantly in the houses, thus explaining its epidemic character. The presence of a considerable number of sandflies so near the houses, but not in their interior, added to the fact that they belonged to a semidomiciliary species, i. e., Phlebotomus intermedius already found before in the interior of the dwellings suggests that chlorophenothane not only kills the flies but repels them. To explain a different result reported by Corradetti in 1952 of the disappearance of sandflies not only from the interior of the houses but also from their vicinity after two chlorophenothane sprayings, the authors emphasize the fact that the sandflies of the region studied (Abruzzo, Italy) are only domiciliary, and apparently breed in the neighborhood of the dwellings, feeding on man and domestic animals exclusively. Since in this case the stables had also been sprayed and there are almost no forests there (and consequently not enough wild mammals), the flies had almost no source of food and disappeared entirely.

The disappearance of the sandflies from the interior of the houses causing the sharp decrease of leishmaniasis to an insignificant level, as observed in the focus under study, enables the authors to predict a similar result in all regions in which leishmaniasis is endemic (the visceral form as well) and where a campaign of domiciliary DDT spraying will be carried out. Therefore, they recommend this method as a basis for leishmaniasis control.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Congenital Absence of Gallbladder.—Excluding patients in whom there were also other malformations of the biliary ducts, only about 75 patients with congenital absence of the gallbladder have been reported in the medical literature. Dr. Luis da Costa Lima, of the Rio de Janiero Hospital dos Pescadores, recently reported three more cases in *Rivista Brasileira de Cirurgia* (**25**:179, 1953). In these patients, two women and one man, icterus was the most prominent symptom, and the correct diagnosis was made only during the operation, as was the case in the patients previously reported. In two of these patients a diagnosis of stone obstructing the ductus choledochus was made, and in the third, the biliary peritonitis was recognized but the diagnosis of vesicular agenesia was not made. In this patient the biliary peritonitis was probably caused by retroduodenal perforation of the ductus choledochus, because inspection of the subhepatic space revealed a flow of small calculi through the epiploic foramen. Therefore, the so-called choleperitoneum without perforation (which was admitted by Buchanan as possible after edema of the extrahepatic biliary ducts, imperceptible rupture of the biliary ducts, or a retroperitoneal biliary flooding), did not occur. According to Mariano de Andrade, who published a report on a patient with congenital absence of gallbladder associated with choleperitoneum in 1949 in Brazil, this condition is extremely rare, since he did not know of another case in the medical literature before his own. The author's case would then be the second of the kind, and probably the first with a clear rupture of the ductus choledochus. The author points out that in his first patient the fossa vesicae felleae was present but empty, and reminds us that, according to Dixon and Lichtman, the fossa vesicae felleae was present in only 7 of 90 patients with vesicular agenesia of all kinds.

Vesicular agenesia has no symptomatology of its own, but abnormalities of the biliary ducts are common in connection with this condition. The ductus choledochus may or may not be dilated even in the absence of stones. In the three patients reported the duct was greatly dilated and contained several stones. In one patient stones were also present in the left hepatic duct. As vesicular agenesia is a condition with symptoms similar to those of lithiasis of the ductus choledochus, especially if accompanied by icterus, the author suggests that, during the operation, the ductus and the adjacent organs should be examined and, if possible, cholangiography with retrograde filling should be performed.

DENMARK

Chemotherapy of Tuberculosis.—Prof. K. A. Jensen and his co-workers have reported that, in cases of pulmonary tuberculosis with cavitation, the administration of isoniazid may produce resistant strains of tubercle bacilli after only two weeks. After three months of treatment with this drug, about 88% of the organisms have become resistant to it. Indeed, when isoniazid is given by itself resistance to it develops almost as quickly as it does to streptomycin. In one series of patients combined treatment with isoniazid and *p*-aminosalicylic acid was given with the result that after three months a tendency to a rise of resistant strains of tubercle bacilli was demonstrable in only 2 out of 13 patients. A month later, 3 of these 13 patients showed isoniazid-resistant strains. The most effective treatment was found to be a combination of streptomycin, *p*-aminosalicylic acid, and isoniazid. The addition of isoniazid to the combination of streptomycin and *p*-aminosalicylic acid did not give rise to any greater discomfort in the patient. At present, treatment with isoniazid alone should be avoided, however tempting it may be to give it at home and without any serious inconvenience. The optimal dosage of the three drugs is being investigated, and it already appears that an appreciable reduction can be made in the dosage of streptomycin without seriously impairing its therapeutic action. Although at one time as much as 3 gm. of streptomycin was given daily, only 1 gm. weekly need be given when it is combined with *p*-aminosalicylic acid and isoniazid.

Sexual Life of Young Danish Women.—Dr. Kirsten Auken, who is the mother of five children, has written a book on the sexual life of women between the ages of 20 and 35. Her material was obtained from three hospitals in different parts of Denmark. She interviewed the patients only when they were about to leave the hospital in order to avoid undesirable gossip in the hospital itself. The physicians in charge of two other hospitals refused their consent to these interviews that were granted with such unanimity by the patients that only 3 out of 318 women refused to partake in them. It was perhaps inevitable that Dr. Auken's work should promptly be called a Danish Kinsey report, but she insists that her methods and findings differ from those of Dr. Kinsey. Her material was gathered from every social class and from many different parts of Denmark. She found that the lower the social class, the earlier the age at which sexual relationships are started, and her findings suggest that the homosexual rate among Danish women is much lower than that discovered by Kinsey in the United States. With regard to the source of information about sexual matters, other women were responsible in 46% and the mother imparted this knowledge in 11.9%; 52% of the women wished that they had been better informed on the subject. In 8.8% sex information was obtained by observing the behavior of animals. Sisters had imparted sex information to another 8.8%, but only 3.1% had been given sex education in school. Respectable publications on the subject had been the main service of information for 5.1%, and pornographic publications for only 1.7%. Many woman, 88.6%, wanted for their children a more adequate sexual education than they themselves had had.

Drug Addiction Problems.—At a meeting of the Copenhagen Medical Society, the problems of drug addiction were discussed. Some of these problems may seem insoluble, but their discussion from time to time helps not only to give a fairly accurate impression of their scope but also to indicate new means that may prove helpful. One speaker referred to a comprehensive analysis he had recently undertaken of about 54,000 medical prescriptions that in the course of a month had been filled by retail druggists. Morphine and opium were numerically the most important drugs prescribed. Amphetamine came next, and meperidine (Demerol) hydrochloride and methadone (Butalgin) hydrochlirode were less popular. Although 40% of the narcotic prescriptions were for morphine or opium, only 2% were for heroin and 2% for cocaine. As was to be expected, many of the prescriptions had been refilled frequently for the same person. The speaker emphasized the practical value of keeping an index file of addicts in Denmark. Another speaker suggested that it should be made illegal to be found in possession of narcotic drugs without a sound reason for it. At present it is only when such drugs are acquired by theft or forgery that their possessors can be prosecuted. If the mere possession of them without justification could be made a criminal offense, it might be possible to prevent addiction in some narcotic users. Another speaker referred to ships' medicine chests as a serious loophole through which narcotics can be obtained. At present any ship's captain can order a supply of such drugs without a physician's prescription. Yet another speaker reported that 56 of 80 patients admitted to hospitals for drug addiction between 1944 and 1950 represented readmissions.

LONDON

Reports on National Health Service.—A detailed account of the working of the National Health Service in England and Wales in 1952 shows a net expenditure for the year ended March 31, 1952, of £348,457,732. At the end of 1952 the number of beds in hospitals was 507,368. The number of inpatients (measured by discharges and including deaths) during the year was 3,414,373, compared with 3,259,214 in 1951. The number of new outpatients increased by 4.9% to 6,605,765. The total waiting list increased by 527 to 500,307. The waiting list for tuberculous patients fell from 7,096 to 6,126. At the end of the year there were 63 mass radiography units in civilian use. In these units 10,654,554 persons had been examined, of whom 3.3 in every thousand were found to have active tuberculosis. Up to the end of the year, about 93,600 persons had been vaccinated with BCG. This figure includes, in addition to contacts, nurses and medical students because of their greater than average exposure.

During the year surgical and medical appliances were provided through the hospital service to the value of £2,980,000. These included 44,991 pairs of surgical footwear, 75,393 abdominal appliances, 35,373 elastic stockings, and 7,255 wigs. The number of new artificial limbs (including replacements) provided since the service began rose from 40,217 to 51,250. The number of invalid chairs and tricycles provided during the year was 12,411, and 7,369 artificial eyes were provided. Hearing aids were supplied to 88,000 new patients, bringing the total supplied since the beginning of the service to 260,000. There was still a wainting list of 66,000.

The total number of blood donations was 647,009, the highest total in any year since 1944, the peak year of the war period. An analysis of how blood was used was made on a 5,000-bottle sample in an industrial city, with the following results: accident cases 10.45%, gynecologic and obstetric patients 19.67%, medical patients 32.23%, and surgical patients 37.65%.

In 1952, the x-ray departments of about 600 hospitals (about half the hospitals with such facilities) carried out 741,000 examinations of patients referred directly by general practitioners. The comment was made that "where the service is available it is certainly not abused and the demand has been less than anticipated." During the year 400 hospital pathology laboratories (just over half the total number in the country) dealt with 554,000 specimens that had been referred directly by general practitioners.

A detailed analysis of general medical practice within the service as of July 1, 1952, showed that there were 17,204 physicians providing unrestricted general medical services, of whom more than half were practicing in partnership with one or more other physicians. There were also 1,689 "permanent" assistants (assistants employed for periods of three or more months) and 309 assistants in training. Twenty-two per cent of the physicians practiced in rural areas, 34% in semiurban areas, and 44% in urban areas. The geographical distribution of general practitioners shows that the towns having fewest physicians per unit population are those in the industrial Midlands, on the north-east coast, in South Yorkshire, and in Lancashire. The areas with the smallest average lists of patients were in the southern half of England, North Wales, and seaside towns. There is a tendency for proportionately more of the physicians in the "under-doctored" areas to be in younger age-groups.

Since the introduction of the National Health Service there has been much talk about the difficulty in assistants in general practice getting practices of their own or in becoming partners. This survey shows that, of 1,689 assistants employed in July, 1952, more than half were employed by physicians practicing alone. Ninety per cent of them were the sole assistants employed by the medical firm in which they were working. Two-thirds of them were aged 35 or under, and most of these had been in their present posts for less than two years; one-fifth of the total were aged 36 or over and had been in their present posts for over two years, and 14% were aged 46 or over. During the second half of the year 51 assistants became principals and 131 became partners in existing practices. Of these, one-half had been assistants for less than a year; a quarter for one or two years; one-eighth for two to three years; and the remainder for longer periods.

During the year 412 alleged breaches by general practitioners of their terms of service were considered by service committees and reported to the ministry by executive councils. In 251 cases the council recommended that no action be taken. In 47 a warning letter was sent, and in the others some action was taken, usually consisting of the withholding of money.

Caution Concerning Cortisone.—A note of caution concerning the use of cortisone in the treatment of rheumatoid arthritis was struck by two of the contributors to the annual symposium on advances in treatment in *The Practitioner* (**171**:346-425 [Oct.] 1953). Prof. D. M. Dunlop of the University of Edinburgh stated: "Although hypercortisonism modifies the reaction of the host to certain agents, it has little or no effect upon the agent itself. In . . . rheumatoid arthritis, the noxious etiological agent may persist indefinitely, and a return of signs and symptoms following withdrawal of the hormone almost invariably ensues. This 'rebound' phenomenon often occurs in a peculiarly virulent form. In such disorders therefore, to effect suppression of the manifestations of the disease, the hormone has to be given indefinitely. The suppressive dose is seldom less than 50 or 75 mg. a day, and unfortunately few patients can be adequately controlled for long periods of time on such doses without eventually developing the undesirable side-effects of hypercortisonism which will necessitate abandonment of treatment. Further, the dose of cortisone adequate to suppress symptoms tends to rise in the course of time and the dangers of sodium retention, oedema and hypertension become greater with advancing years. Prolonged treatment is liable to cause osteoporosis, sometimes manifested by the sudden collapse of a vertebra. Thus, the longer an induced hypercortisonism is sustained, the more are injurious side-effects likely to be encountered. In these circumstances the ethics of relieving symptoms temporarily with cortisone must be seriously questioned in any patient in whom the noxious etiological agent is likely to persist permanently. Indeed, in rheumatoid arthritis there is some evidence that in the long run the ultimate state of patients controlled by cortisone is no better than those controlled by adequate doses of aspirin."

A similar attitude was adopted by Dr. William Tegner, London Hospital, who said, "The advocacy of these new [agents] . . . has led to enthusiastic trial [which] . . . must be expected so long as rheumatoid arthritis remains a disease of unknown etiology and doubtful prognosis. Both doctor and patient are quite naturally eager to clutch at straws . . . But after early hope and optimism, disappointment inevitably follows. . . . Cortisone and ACTH can have a profound and gratifying effect in suppressing the activity of rheumatoid arthritis but . . . this early effect may need progressively larger doses for its maintenance and . . . prolonged treatment may bring with it a host of difficult and even dangerous side-effects. . . . It has been suggested that the rôle of cortisone and ACTH is to tide the patient over until a natural remission has set in; but one can never foresee when a remission will occur and too often dangerous side-effects have become apparent before any remission has manifested itself. These difficulties are especially prominent in elderly patients and in post-menopausal women, who seem to tolerate prolonged treatment with these hormones very badly."

Potassium Permanganate as an Abortifacient.—Five new cases of vaginal ulceration following the insertion of potassium permanganate for the purpose of procuring abortion were reported by E. A. J. Almett and C. S. Nicol (*Brit. M. J.* **2**:759, 1953). Three had vaginal bleeding, one a brownish vaginal discharge, and one pain, dysuria, and swelling of the vulva. Four of the patients were found to have the characteristic apposition vaginal ulcers produced by potassium permanganate. Four gave a history of inserting tablets to achieve abortion; the remaining one admitted only using a solution of tablets in a douche. Bleeding occurred in all five, but in none was packing or transfusion necessary, although ligation of a bleeding artery was necessary in one. Abortion as a result of the use of the tablets did not occur in any of the patients. Three first attended a gynecologic outpatient department, and two a venereal diseases clinic. The main difficulty in diagnosis is confusion with primary syphilis, as the ulcers may be mistaken for contact chancers. The common use by women of potassium permanganate in tablet form for procuring abortion and the ease with which it may be obtained were stressed. Tablets of potassium permanganate are readily obtainable from pharmacists, and there is no restriction on their sale.

New Developments in Radiotherapy.—News has just been released of the installation of a linear accelerator and a cyclotron in the Medical Research Council Radiotherapeutic Unit at Hammersmith Hospital. The radiotherapeutic unit occupies the end wings and three stories of the central block. The two-story north wing houses a 45-in. cyclotron; and the single-story south wing houses an 8 mev linear accelerator. The fourth floor of the central block is occupied by a hospital research department. Four more stories of the central block (yet to be built) will be occupied by the London University Postgraduate Medical School. Each wing was designed as a self-contained unit to be linked up with the central block containing laboratories. The cyclotron suite was planned to go above ground and not below ground as is sometimes done to provide protection against radiation. In the case of both the cyclotron and the linear accelerator protection is provided by reinforced concrete walls and roofs about 6 ft. thick. The main doorway to the cyclotron chamber is formed with an electrically operated 35-ton door consisting of a steel box filled with concrete. The door between the cyclotron chamber and the assembly bay is a 190-ton electrically operated, horizontally moving door of reinforced concrete.

The linear accelerator is a direct descendant of radar, and provides another example of wartime discoveries being applied to medicine. It has been developed by the Atomic Energy Research Establishment in colaboration with the Medical Research Council Radiotherapeutic Unit and makes use of the frequency magnetron that is the basis of radar. It receives its name from the fact that it accelerates a beam of electrons down a straight tube (3 m. in length), and in this process a voltage of 8 million is attained. The beam has a very short wave length and a relatively great penetrating power, and it is hoped that it may prove of value in the treatment of deep-seated malignant growths. From the point of view of handling, it is as compact and as easily handled as the ordinary deep x-ray units of 200,000 volts now in general use. The one that has been installed at Hammersmith is the first of its kind to be used for clinical purposes, and the results of its use are awaited with much interest. It is reported that the Ministry of Health has already placed orders for several 4-million volt units for installation in various hospitals throughout the country.

The cyclotron, which is still in the process of construction, is the first cyclotron in this country to be built in a hospital. Its potentialities in medicine are still not clearly defined, but two uses are immediately indicated. One is for the production of radioactive isotopes of such a short life that they can be used only for therapeutic or research purposes. The other is to determine whether the neutron radiation of the cyclotron has any advantages over other forms of radiotherapy in the treatment of malignant disease.

The Physician's Office.—Within a fortnight of the publication of the report of the British Medical Association committee on general practice, a letter was sent by the general medical services committee of the British Medical Association to every general practitioner in the National Health Service, "earnestly hoping that [he] will do his utmost to provide the highest possible standard of surgery and wainting-room accommodation for his patients." The opinion is expressed that the general standard is of a high order, but "a number of general practitioners have, by reason of building restrictions and the high cost of repairs and maintenance, been prevented from doing all that they would have wished in this respect." It is pointed out that under his terms of service a practitioner at his own expense "is required to provide proper and sufficient surgery and wainting-room accommodation for his patients" and that any member or officer of the executive council or local medical committee can, under the regulations, inspect the accommodation provided. Further, a practitioner's remuneration in the National Health Service takes into account his obligations to provide suitable premises, and it remains his personal responsibility to provide them at his own expense.

Physicians should review the surgery and wainting room accommodation in their practices for the following reasons: 1. There has been a general relaxation in building restrictions. 2. Health centers are unlikely to be built on a large scale for a long time to come. 3. As a result of the Danckwerts award, general practitioners are in a better position to embark on such expenditure. 4. The practice expenses ratio established by the Danckwerts award includes a substantial element in respect of the cost of maintaining surgery premises. The committee does not consider it either practicable or desirable to lay down any minimum standards. It believes that any necessary improvement in the standard of accommodation provided should develop spontaneously from a wish by the physicians concerned to ensure that their offices are compatible with the prestige and status of general practice in the service.

SWITZERLAND

International Congress of Rheumatic Diseases.—The Eighth International Congress of Rheumatic Disease was held in Geneva Aug. 24-28. Over 1,000 rheumatologists from about 40 different countries, including the U. S. S. R., attended. The welcoming address was delivered by Prof. K. M. Walthard, president of the organizing committee. Dr. Knutti, of the National Institute of Arthritis and Metabolic Diseases, Bethesda, Md., told of the fight against rheumatic diseases in the United States. A series of reports was devoted to the study of the relations between rheumatism and conjunctival tissue. Professor Nesterow of Moscow expounded the theory that rheumatism is an infectious-neurogenic reaction in which disturbances in the floor of the diencephalic neurovegetative centers play a large part. Professor Reichstein, from Basle, spoke on the chemistry of hormones of the adrenal gland, and especially hydrocortisone (17-hydroxycorticosterone) and desoxycorticosterone. His synthesis of these hormones a few years ago brought him the Nobel prize in medicine. He then announced the discovery of a new compound provisionally named electrocortine. This substance is closely related to desoxycorticosterone and its physiological and pharmacological action is said to be 30 to 40 times more powerful. Its place in the treatment of rheumatic diseases has not yet been definitely determined. Dr. Philip Hench, from the Mayo Clinic, reported on the therapeutic use of cortisone and corticotropin (ACTH) in rheumatism. He warned against the abuses of cortisone, described the prevention and the treatment of hypercorticism, the methods of interruption of the treatment, and the prevention of acute adrenal insufficiency in patients treated by these hormones who might have an increased reaction to stress as a result of a serious infection, a trauma, or a surgical operation. Professor Goslings set forth the criteria needed to evaluate the degree of action of a preparation of corticotropin in man. This study showed the difficulties of testing the activity of this hormone and the necessity, during a clinical study, to use a single source of hormone.

These five days of scientific work were pleasantly interrupted on Aug. 26 by a journey to Aix-les-Bains, the well-known French center for the treatment of rheumatism, where clinics were held for the visitors. As the scientific sessions continued, the two protagonists of the introduction of plastic material for the reconstruction of diseased femoral heads, Prof. Merle d'Aubigné and Dr. Judet, of Paris, presented the results of seven years of experience. In a series of 500 cases of coxitis, Dr. Judet observed good results that have been maintained for several years in 65% of patients. Many of these patients who had been invalids were enabled to walk and some even to return to their work. Because of the tendency to remissions and the progressive nature of polyarthritis, the rehabilitation of patients is difficult. Bennett, of the International Labour Office in Geneva, spoke of the efforts of this organization to find for the patient employment best adapted to his remaining abilities.

Prof. Maurice Roch Retires.—Prof. Maurice Roch, who has reached the age limit for teaching, will leave the faculty of medicine of Geneva University in October. He will be remembered for his book "Dialogues Cliniques" and for his approach to the patient as an individual rather than as a specimen. Professor Bickel, a disciple of Professor Roch, will succeed him.

CORRESPONDENCE

THE KINSEY REPORT

To the Editor:—The newer findings concerning physiology of the pubococcygeus muscle strike at the very roots of the conclusions implied by the Kinsey report. Even if the statistical data were unassailable, Kinsey's interpretation is based on concepts that have long been controversial. This applies particularly to the question of vaginal and clitoral orgasm. I believe, as many others do, that research in the physiology of the pubococcygeus muscle has produced overwhelming evidence in favor of the existence and importance of vaginal orgasm.

Kinsey stresses the subject of conditioning, especially in relation to premarital experience. Obviously, if conditioning emphasizes clitoral stimulation, the problem of future satisfactory sex relations is aggravated. I believe, if this fundamental error in Kinsey's understanding of orgasm is adequately exposed, considerable doubt will be thrown on the accuracy of his conclusions. The necessity for mitigating the impact of the Kinsey report on the public is illustrated by a recent radio discussion on juvenile delinquency. Judge Bernstein of Los Angeles stated that it has become difficult to answer delinquent girls who brazenly quote the Kinsey report in order to justify their actions. Similar observations have come from probation officers. A former president of the California Bar Association remarked that judges are looking for well-founded medical opinions to counter the irresponsible use of the Kinsey report.

Parents find themselves in the same dilemma, and they will appreciate well-presented physiological knowledge that will help them guide their children. It is possible that many youngsters, who do not understand the importance of moral and legal restraints, may accept the advisability of avoiding behaviors that are detrimental to their future sex appreciation, happiness, childbearing functions, and prevention of so-called "female complaints."

Now as to Kinsey's book. For the stated purpose of his research, i. e., establishment of a basis for the revision of existing sex laws, Kinsey applied the statistical method, which is widely accepted in the social sciences. This is not the place to go into the question of whether material gathered by that technique is significant from the medical point of view. We must, however, take cognizance of the fact that histories based on interviews were collected during a 15 year period prior to Jan. 1, 1950. It appears that the standardized questions were formulated on the basis of information available at onset of the inquiry, approximately 18 years ago.

With regard to the anatomy of the pubococcygeus muscle and the sexual physiology of the vagina, the decisive discoveries were published only subsequent to that time. In February, 1939, Curtis, Anson, and McVay presented (in *Surg, Gynec. & Obst.)* completely new findings concerning the anatomy of the pubococcygeus muscle. In particular, Anson demonstrated the presence of minute terminal interdigitating fibers inserting in the wall of the urethra and of the middle third of the vagina. Anson stated that all previous descriptions of pelvic anatomy are either incomplete or erroneous. Anson's work on the pelvic anatomy became more readily accessible in the fifth edition of Curtis' "Textbook of Gynecology" (1947) and subsequently in Anson's "Human Anatomy" (1950). Kinsey's statements are based on the assumption that the vagina is insensitive because its superficial tissues contain few if any sensory nerves; on the other hand, his material indicates that satisfaction is, in a certain percentage of cases, obtained from vaginal penetration during coitus. He assumes the presence of a "mechanism that lies outside of the vaginal walls themselves" (page 581). Kinsey states further "that the deep penetration of the rectum may bring satisfaction which is, in many respects, comparable to that which may be obtained from a deep vaginal insertion" (page 581). His report that anal and deep vaginal feeling are parallel can be explained by the anatomic arrangement of the pubococcygeus, which surrounds both organs. My clinical studies have led me to conclude that within the pubococcygeus there exist highly specialized proprioceptive nerve endings. Any sensation received by these proprioceptors must differ from that derived from superficial innervation.

The pubococcygeus varies widely in different women, independent of age or childbearing. Roughly speaking, one-third of all women have a strong pubococcygeus, another third have a weak and atrophic pubococcygeus, while the rest can be described as borderline cases. The status of the pubococcygeus shows a definite relationship to the various functions of the muscle, i. e., support, stretching during parturition with subsequent return to normal, bladder control, and sexual response.

It is interesting to refer to a paper by John W. Huffman (The Effect of Gynecologic Surgery on Sexual Reactions, *Am. J. Obst. & Gynec.* 59:915-917 [April] 1950). who found that various gynecologic operations, including removal of the clitoris, did not interfere with sexual activity in mature women. Huffman states: "This study would tend to bear out the assumption that the vagina becomes the center of normal sexual activity in the mature female. . . . Sexual stimulation increases engorgement of the genitals; as a result of physical contact vaginal sensory organs are stimulated. These stimuli produce vaginal contractions and spasmodic muscular movements which culminate in a phenomenon comparable to the male orgasm, but without the discharge of retained secretions."

Kinsey remarks, on page 580, "The relative unimportance of the vagina as a center of erotic stimulation is further attested by the fact that relatively few females masturbate by making deep vaginal insertions." This statement is significant, as Kinsey consistently uses response to masturbation as the measuring stick of orgasm. Of further interest are the figures in table 23 (page 178) concerning the incidence of masturbation in married women. The figures lie between 23 and 36%, with a rough weighted average of 33%. It is noteworthy that examination of many thousands of women has shown that the pubococcygeus is weak in about one-third of them. It is my impression that the same third masturbate during married life, because weakness of the pubococcygeus renders them unable to receive sexual satisfaction from coitus. Many of our patients abandoned clitoric stimulation and masturbation as soon as function of the pubococcygeus was improved.

I have found that women who depend on clitorolabial stimulation are as a rule not aware of the presence of the pubococcygeus and of the possibility of contractions of this muscle. In the restoration of function of the pubococcygeus, it is of decisive importance that awareness of the muscle be established as a first step. In several publications I have stressed this point. A surprising finding is that mere awareness of the pubococcygeus and its contractility tends to improve its various functions. This applies also to sexual appreciation, which may thus be enhanced even before active exercises are instituted. In many women with borderline problems of lack of disturbance of vaginal feeling, it is sufficient to identify the pubococcygeus for the patient and to inform her of its contractile and sensory potentialities. Concentration on the muscle seems to cause patients in this group to forget the clitoris.

Naturally, the question must arise as to why the pubococcygeus shows such great variations in women. It should be mentioned that, among the thousands of women examined at Los Angeles County General Hospital and in private practice, there were women from various races and extractions, including Negroes, Mexicans, Chinese, and others. No differences could be established on the basis of national or racial origin. The explanation must, therefore, be looked for in the phylogenetic character of the pubococcygeus. The former "tail-wagger" lost its principal means of exercise when the human being assumed the upright position, while at the same time a new function, pelvic support, was added. The pubococcygeus, along with the quadriceps and rectus abdominis, is an old muscle in transition, prone to atrophy of disuse. It must be maintained in a state of tone and vitality through conditioned reflexes.

Seventy-five per cent of women with urinary stress incontinence during adult life present a history of difficulties with micturition in childhood. This finding indicates that the development of a strong pubococcygeus is related to training in sphincteric control, both anal and urinary. The sexual function of the pubococcygeus is superimposed on these sphincteric and supportive functions acquired earlier. It is very improbable that vaginal feeling can be established in a poorly developed pubococcygeus at the time of first intercourse, be it gentle or rough; but subsequently the sexual function may be developed in some cases. The response of a strong pubococcygeus to the quality of first intercourse is not consistent. In some women sexual conditioning is brought on in spite of a rough first experience, but as a rule a gentle, gradual technique is more conducive.

Kinsey stresses premarital experience as important for sexual appreciation, without reference to the quality of early experience. In view of the physiological facts concerning the pubococcygeus muscle, Kinsey has missed the most important point completely. The effect of early experience depends on the factors associated with coitus as an expression of true love, which Kinsey ignores throughout his book. A first experience, whether marital or premarital, that begins with rape and fear and under uncomfortable or immoral circumstances is hardly conducive to conditioning of the highly sensitive vaginal function. Conditioning of response exclusively to clitoral stimulation interferes with the development of vaginal feeling.

ATRIUM AND AURICLE

To the Editor:—It is extremely gratifying, at long last, to note that "official" recognition has been given to the general misuse of the word auricle in well-known clinical entities such as atrial flutter, atrial fibrillation, atrial septal defects, and atrioventricular block. The recent (fifth edition, 1953) "Nomenclature and Criteria for Diagnosis of the Heart and Blood Vessels" published by the New York Heart Association and distributed by the American Heart Association has finally discarded auricle for atrium wherever the upper chambers of the heart are concerned. This is a delayed but welcome concept that has been ignored in previous editions of this valuable manual.

About 25 years ago I joined with the late Dr. A. E. Parsonnet in an endeavor to correct the traditional misuse of the word auricle in describing the atria of the heart. Our objections were based on the very definition of the word: "Auricle [L. auricula, the external ear]. 1. The pinna of the ear; the ear flap or external ear. . . . 2. An appendage to the atria of the heart; auricular appendix. 3. Any ear-shaped structure or appendage. 4. Commonly used mistakenly for atrium" ("Blakiston's New Gould Medical Dictionary," Phila delphia, the Blakiston Company, 1950, p. 109). In a previou communication ("Discarding of Out-Dated Medical Terms, *J. A. M. A.* [July 5] 1952) I originally included the wor auricle in the list of medical terms that had out-lived thei initial concept, but it was omitted in favor of such old tim favorites as water hammer pulse and hobnail liver. Ther appeared to be a general reluctance among most clinicians t abandon a word as familiar as auricle, although its misus was well recognized by all teachers of medicine.

The more or less rapid change from auricle to atrium i medical thinking during the past few years has been du chiefly, I believe, to the advances made in cardiac surger On the operating table the auricle is definitely an appendag to the upper chamber of the heart; it is not the enti chamber. As a technical procedure it became necessary f the surgeon to differentiate the atrium as a whole from th auricle; in mitral commissurotomy the left auricle is sometim amputated and removed. This surgery would be impossib under the traditional use of the word.

The obvious purpose of this communication is to point o the need for a prompt acceptance of the word atrium in plac of auricle in all future medical literature. The words are n longer colloquially interchangeable. The auricle, insofar a the term refers to the heart, is an appendage to the atriun The terms auricular flutter, auricular fibrillation, and the lik no longer serve any useful purpose.

New York Medical College
450 E. 63 St., New York.

QUININE IN TONIC WATER

To the Editor:—Cinchonism is relatively rare in the Unit States both because of the low incidence of malaria and b cause of the use of the newer antimalarial drugs when ind cated. I think it worth while to present to your readers th following unusual reaction because of the increase in pop larity, at least in the east, of the drink "gin and tonic."

I saw a 43-year-old man in consultation who had a seve week history of tinnitus and hearing loss. He had consulte an otologist, who found bilateral diminution in hearing, an a neurologist, who suggested the diagnosis of bilateral angl meningioma. Because of the history of daily ingestion of seve to eight drinks per day he was sent for a medical evaluatio prior to further workup for neurosurgery. The history o alcohol ingestion was correct, but his diet was in general ad quate. After a physical examination, which was not remark able except for the facts already noted, casual discussio brought out the fact that the drinks were always gin and tonic Since I had seen cinchonism in the southwest Pacific, I though it worth while to change the beverage to Tom Collins. Withi 48 hours the symptoms had disappeared. A test dose of 30 mg. of quinine brought a return of the tinnitus. Later, a tes dose of 150 mg. produced the same effect. Three weeks afte the discontinuance of the quinine, audiogram showed restora tion of hearing.

While I have not obtained the exact formula of quinin water, I am informed that the Schweppes brand contains abou 30 mg. per pint. The man was ingesting about 100 mg. daily It is clear that it would take an enormous consumption t produce the symptoms in the normal adult, but the existenc of idiosyncrasy is well known, and this source of suppl seems, therefore, worth publicizing.

CHROMATE HAZARDS IN INDUSTRY

Edmund N. Walsh, M.D., Fort Worth, Texas

The element chronium was identified in 1797. Within 30 years, chromium compounds were mentioned in the medical literature as a cause of ulcerations and dermatitis in the workers who used them.[1] Today chromium and its salts are widely used in industry and are being used in ever-increasing amounts. The purpose of this paper is to mention some of the important industrial uses of chromium and to discuss the medical problems of its use, particularly chromate dermatitis.

Chromium and its compounds are obtained from chromite ore, which is a mixture of iron and chromium oxides. It is a gray metal, with a melting point of 1,890 C and great resistance to corrosion. It has valences of 2, 3, and 6 and forms both chromium salts and chromates. The bivalent chromous salts are unstable and of no commercial importance. Chromic oxide (Cr_2O_3), a green pigment, and chromic sulfate ($Cr_2[SO_4]_3$), which is used in tanning, are trivalent chromium compounds. The hexavalent compounds, such as sodium dichromate ($Na_2Cr_2O_7$), are the most active chemically and the most widely used. They probably are the only forms that pose any problem from an industrial health standpoint.

COMMON USES IN INDUSTRY

The following paragraphs consist of a brief discussion of some of the commoner uses of chromium compounds in industry and the various medical complications, such as systemic intoxication, perforated septum, chrome ulcer, and dermatitis, that may arise during such use. These medical aspects, particularly the dermatoses, will be considered in detail later.

Chromium plating for decorative and anticorrosive coatings is an electrolytic process in which metallic chromium is deposited on the cathode from a solution of 20 to 40% chromic acid contained in an open tank. Hydrogen is liberated at the cathode, and the hydrogen bubbles rising to the surface produce a mist of chromic acid. When this mist is inhaled, it first comes in contact with the mucous membrane of the lower nasal septum, sometimes causing ulceration and later perforation.[2] If concentrated mists reach the lungs, acute pulmonary symptoms may result.[3] Recently, possible chronic hepatic intoxication from prolonged inhalation of these mists has been reported.[4] Contact with the mist or solutions will, of course, also cause dermatitis in sensitive persons or high concentrations may even cause a primary irritation. In large scale operations, such as in plating automobile trim, the procedures are almost completely automatic, so that few workers are exposed to the acid. Today proper ventilation and exhaust ducts minimize the danger in most shops. It is in the smaller plating establishments where protective measures are not strictly enforced that trouble occurs. Workmen handle pieces just removed from the chromic acid solution, and frequently the solution is spilled or dripped on the floor. Sweepings from the floor of one small plating shop contained 10% chromium, which would be equivalent to 20% chromic acid. Most workers in the plating industry are familiar with the chrome sore, perforated nasal septum, and chromate dermatitis, and few even consult a physician about the first two conditions. If a chromate dermatitis develops, however, the worker usually must leave the trade, since complete avoidance of contact is difficult because of the contaminated work area.

Anodizing is another electrolytic type of anticorrosive metal treatment, used principally on aluminum. Almost all aluminum airplane parts are so treated. Baths of 5 to 10% chromic acid are used, and the metal to be treated is the anode. An anodic film of aluminum oxide is formed on the metal, which serves as a protective coating in itself or as a base for the application of zinc chromate priming paint. Zinc chromate paint is a common cause of dermatitis in the aircraft industry. The chromic acid mists evolved by the anodizing process are much less concentrated than those formed in chrome plating. Thus, the danger of the occurrence of perforated septum or toxic effects from inhalation is much less, although chrome ulcers and dermatitis have occurred. Other anticorrosive treatments involve only the immersion of metals in baths of various chromate solutions for the formation of anticorrosive films. Dermatitis and possibly chrome ulcers may be encountered but have not been reported in the literature.

In the processing of chromite ore to produce chromium compounds, considerable dust is formed, which contains monochromates and dichromates. While systemic intoxication has not been reported, there seems to be a long-term hazard of carcinoma of the lung from inhalation of this dust.[5] Perforated septums and chrome sores are common in these workers.[6] Dermatitis has been seen infrequently. Dust control measures have been adopted to eliminate the more serious hazard of pulmonary carcinoma.

Despite the fact that the steel and refractory industries use more than 80% of the chromite ore, no instance of dermatitis has been reported among them, since trivalent and metallic chromium apparently are not irritating or sensitizing substances. Chrome steel may contain from 0.5 to 35% chromium. A dermatitis due to chrome steel identification tags has been reported,[7] and chrome-plated metal has been cited as causing chromate dermatitis.[8] These observations were not, however, checked by proper patch testing and are not definitely known to be reactions to metallic chromium or chromate. Refractory grade chromite ore is used to make bricks for the lining of steel furnaces.

Since the early 1930's chromates have been used for the control of corrosion in various types of recirculating water systems. They are so effective in this capacity that their use is standard in diesel railroad locomotives. They are also used in some other internal combustion engines, in refrigeration systems, in the brine in ice plants, and in some air conditioning installations. Their use for the same purpose in oil well mud, gas wells, and pipelines is rather limited at present. The chromates are used in dilute solution in this capacity, in concentrations ranging from 100 to 2,500 ppm (1/10,000 to 1/400), but this concentration is still above the threshold of sensitivity for some persons. Leaks about pumps and couplings may contaminate the whole work area with the chromate solution, and by evaporation more concentrated residues are formed. Dermatitis[9] and possibly chrome ulcers have been reported as complications from this use.

Zinc chromate primer, commonly called "prime," is used as a corrosion-inhibitive paint on most aluminum and magnesium airplane parts after anodizing. With employment in the aircraft industry at a high level once more, workers using this paint probably constitute the largest group currently exposed to chromates. Although the zinc chromate is found in dust in the plant and is sprayed in the form of paint on many of the airplane parts, there has been no report of a perforated septum or systemic reaction among workers in the industry. Dermatitis is frequently seen.[10]

Chrome tanning as an improvement over vegetable tanning for certain kinds of leather achieved commercial significance about 1900. Trivalent chromic sulfate and in some processes hexavalent sodium dichromate are the materials used. Chrome sores and chromate dermatitis were found early to be an industrial hazard in this field. At present, their incidence has been reduced by protective measures and by the substitution of mechanical for manual handling of the hides where possible. Three-quarters or more of the leather in the United States is tanned by this process. These leathers contain 3.9 to 6.9% chromium as chromic oxide in hide substance, i. e., minus water and fat. Theoretically, when tanning is completed, all this chromium is in trivalent form in close chemical combination with the hide protein. Since apparently trivalent chromium is never sensitizing, the frequent coexistence of dermatitis from shoe leather and hypersensitivity to chromate is difficult to explain. There are several possible explanations: There may occasionally be small amounts of residual chromate that was not reduced during the "two bath" tanning process. Some of the trivalent chromium may be oxidized to chromate during some subsequent processing of the leather. Chromate may be used in the dyeing of some leathers. Finally, there may be some peculiar relationship between shoe leather dermatitis and positive reactions to chromate patch tests, such as has been found in cement eczema.[11] Further studies should be carried out to clarify these points.

Large amounts of chromate are used for wood preservation. The solutions contain chromated zinc chloride, and some exposure of the workers occurs. The wood is impregnated with the chemicals, which may be a hazard for those handling it. There has been no report of dermatitis in this industry or from this material.

In photoengraving, ammonium dichromate is used as a photo sensitizing agent[2] and often is handled rather carelessly. Here again a large part of the shop area may be contaminated to some extent with dried chromate. This material is used for the same purpose in lithography.[2] In blueprinting a bichromate bath is used for fixing the color in the paper. Finished blueprint paper has a small percentage of chromium compound in it and may cause dermatitis. One analysis of this paper showed 0.024% chromium, some of which is in hexavalent form. In all these trades, as in chrome plating, chrome dermatitis is well known, and most workers know of someone who has it or who has had to leave the trade because of it.

Sodium bichromate is used extensively as a mordant or fixative for the dyeing of woolen cloth and fur. A dermatitis from this use has been observed in wool mill workers.

Except for zinc chromate, mentioned previously, the pigments used in paints, inks, rubber, and ceramics, namely, lead and barium chromate and trivalent chromium oxide, are very insoluble and seldom if ever cause dermatitis. These substances may sometimes contain traces of a soluble hexavalent chromate that will cause difficulty in the evaluation of patch tests.

The chief fields in which chromium salts are used extensively have been mentioned. They are also used in the manufacture of dry cell batteries, matches, and explosives, in fur and leather dyeing, in bleaching of fats and oils, and as reagents in the chemical industry. The foregoing discussion is, however, sufficient to indicate that chromate materials are widely used and that physicians should always be alert to the possibility of their being the cause of an occupational dermatosis.

MEDICAL ASPECTS OF CONTACT WITH CHROMATES

The medical aspects of contact with chrome compounds were reported in the literature as early as 1827.[1] Acute toxic reactions rarely occur except from accidental ingestion or the inhalation of concentrated mists such as are formed in electroplating.[8] After ingestion, symptoms usually appear in a few minutes or a few hours and are abdominal pain, vomiting, and diarrhea.[12] Traces of albumin are found in the urine. Toxic changes in the kidneys and the liver have been described.[13] Most patients have recovered without sequelae.

Inhalation of concentrated mists causes pulmonary congestion, with fever, cough, and production of sputum.[8] Productive cough may persist for as long as one year. The occurrence of toxic hepatitis, with jaundice and severe liver damage, has recently been reported in one worker and evidence of mild hepatic dysfunction in three others in the same group who were exposed over long periods to mists from a plating tank.[4] Excretion of chromium in the urine could be demonstrated in these patients.

Inhalation of chromate-containing dust by workers in ore processing plants over long periods (15 years) seems to have a carcinogenic effect on the lung. Pulmonary carcinoma occurred 16 times more frequently in these workers than in comparable groups.[5] While the series was not large, the figures are apparently significant. Similar observations have not been reported from any other industry in which chromate is used.

CHROME ULCER AND PERFORATED SEPTUM

Other types of lesions that are of more interest to the dermatologist are the chrome ulcer and perforation of the nasal septum. Perforation of the nasal septum obviously can occur only in shops in which there are mists or dusts containing chromate. First, a painless ulcer appears on the lower cartilaginous portion of the nasal septum. In as short a time as one to two months a perforation may develop. These lesions usually cause little or no discomfort, and the patients seldom consult their physician about them. Edmundson found 61% of 285 workers in a primary chromium chemical manufacturing plant to have perforated septums.[6]

Chrome ulcers are well known in the tanning, electroplating, and chroium-chemical-producing industries. They form only when the chromate is introduced into a break in the epidermis. Thus while the hands and arms are the commonest sites, the ulcers may occur anywhere on the body. In the aforementioned chemical plant, 69.5% of the workers had chrome ulcers or scars of such ulcers.[6] The typical ulcer has definite characteristics. It is a punched out lesion, 2 to 5 mm. in diameter, with a raised collar-like indurated border several millimeters wide. It tends to take the shape of the preceding break in the skin. There is minimal inflammation, and the lesions are relatively painless, except when near a joint or subject to trauma. They usually heal, leaving a depressed atrophic scar, although hypertrophic scarring has been seen. No instance of malignant degeneration has been reported in a chrome ulcer or in a septal perforation. There apparently is no increased tendency on the part of workers in whom these lesions develop to become sensitized to chromates.[6] No reports were found in the literature on the amount of exposure or the concentration of chromate needed to produce an ulcer. The simple tests reported in the table give some information on these questions. All tests were made by the usual patch test technique, except that the materials were placed on scratches about 2 mm. long that were made with a knife point inserted just deep enough to draw blood. These observations suggest that very low concentrations of chromate may, under the proper conditions of time and contact, produce ulceration. The ulcers apparently are due to a toxic, necrotizing action of the chromate ion on living tissue, independent of its sensitizing properties. There was no allergic reaction or primary irritation with 0.5% dichromate on intact epithelium in the patient on whom the tests were done. At the higher dilutions, the acidity or alkalinity of the solution could not be responsible. It is interesting to note that solutions of the monochromate salts of sodium and potassium are alkaline in reaction but that the dichromate salts are acid, yet they act identically in the production of an ulcer or dermatitis.

CHROMATE DERMATITIS

The sensitization to chromate compounds that results in dermatitis is of great importance to industry and to dermatologists. It is difficult to judge from the literature how great the hazard is. It has been reported that as many as 25% of

workers exposed to chromate in a lithographing plant had chromate dermatitis during the first year.[14] This incidence is certainly higher than that in any other group studied. Schwartz and Dunn found that 4% of workers who maintained an air conditioning installation in which chromate was used in the circulating fluid had positive reactions to 3% dichromate in patch tests; however, not all of the reactors had dermatitis. From the data in Hall's paper, "Occupational Contact Dermatitis Among Aircraft Workers,"[8] it would seem that in 5 to 6 workers out of every thousand a chromate dermatitis due to zinc chromate primer paint develops each year. Ellis, in a similar group, estimated the incidence at about one per thousand per year.[10b] Rough estimates of sensitivity made from data from another large aircraft factory that has about 12,000 workers in contact with the same material agree with Hall's findings. In a small group of diesel locomotive workers that I studied the rate was about 10 per thousand per year, or 1%.[9] It would seem from the above that the probable limits of incidence of dermatitis in any large group of persons exposed to hexavalent compounds will be between 1 and 10 per thousand per year. This will probably vary greatly with the type of exposure and the turnover of employees.

It would be well here to amplify and substantiate as far as possible the statement made several times in the paper that only the hexavalent chromate ion is a sensitizer and that metallic chromium or the trivalent compounds are not sensitizing substances. There were no reports in the literature examined suggesting that a hypersensitivity reaction to trivalent chromium occurs. The one report of reaction to metallic chromium[7] was not proved by proper patch testing and may well have been a reaction to nickel. Several dermatologists of wide experience in industrial dermatology and cutaneous allergy stated that they knew of no report or instance of reaction to trivalent chromium. Three patients were tested who had positive patch tests to very weak solutions of bichromate (1/10,000 and 1/20,000) showed no reactions to solutions of trivalent salts[11] nor to metallic chromium. Three-fourths of all shoes are made with chrome-tanned leather containing 3 to 6% trivalent chromium. The wearing of shoes made from this leather is, in effect, a mass patch test to trivalent chromium. No instance of sensitization has ever been reported. These facts give a substantial basis for the assumption that sensitization to trivalent chromium or metallic chromium does not occur.

There is little in the literature regarding the incidence of chromate sensitivity in the general population. In a group of eczema patients 12% were found to have positive patch tests for chromate. In a group of patients with other dermatoses 5% had positive reactions.[14] Among 60 patients in a tuberculosis sanitarium, I found three with a definite positive reaction to 1% postassium dichromate. This is about a 5% incidence of definite positive reactions. Only two, or 3½%, gave a definite reaction to 0.5% dichromate. In another group of 60 hospital patients tested with 0.25% dichromate there were no positive reactions. These groups are all too small to be statistically significant but it would appear that there is a higher incidence of positive patch tests to 0.5% or 1% dichromate in the general population than of dermatitis in industrial workers exposed to chromate. Perhaps 0.25% dichromate would be a better test dilution to demonstrate the more marked degrees of hypersensitivity.

Little is known of the factors influencing sensitization. The concentration of the material seems to play little part. It would seem likely that there would be a high incidence of sensitization among the workers in the chromium-chemical-producing plant who had the high incidence of ulcers and perforated septums and who obviously were often exposed to heavy concentrations of chromate. Edmundson found only 2 of 56 of these workers with ulcers or septal perforations who had a positive 24-hour patch test to 0.5% sodium dichromate.[6] These two gave a history of dermatitis but did not have it at the time of examination. This represents only 3.5% of the group, or about the same incidence that was found in the previously mentioned sanitarium patients who were tested with the same material. This is a higher incidence than was found in the other industrial groups, but again these groups are too small for an accurate evaluation. Some investigators in this field feel that dilute solutions are more likely to sensitize.

An interesting work was recently reported in Switzerland by Jaeger and Pelloni, who found that 30 of 32 patients, or 94%, with cement eczema had a positive patch test to 0.5% dichromate. Traces of chromium were demonstrated in several samples of cement that were tested. The type of chromium found was not mentioned, and no explanation of this peculiar clinical finding was advanced.[11]

Only general statements can be made about the effect of the duration of exposure on sensitization. Most men seem to agree that the great majority of exposed workers who will develop a sensitivity do so during the first nine months they work with chromate.[14] However, dermatitis may appear in one week or not until after as long as nine years of exposure. A most important point is that sensitization does not increase in proportion to the duration of exposure.

The reaction threshold of those sensitive to chromate may be very low. One patient with a shoe leather dermatitis reacted to a 1:20,000 solution of sodium dichromate. For routine patch testing, 0.5% dichromate is the recommended strength. Ellis felt that this strength might give questionable or negative reactions[10b] and suggested a 5% chromate solution. As mentioned above, 0.25% may give a more accurate test of hypersensitivty. When a high degree of sensitivity is suspected, a 0.05% solution should be used as a first test and even this may give a 3+ reaction. Delayed positive reactions that do not appear for 24 to 48 hours after the test period are sometimes seen and should be routinely watched for.

Results of Patch Tests with Various Concentrations of Chromium Compounds Applied to Superficial Skin Abrasions

Material	Length of Exposure	Reaction			
Chromic acid, 2%	24 hours	Crusted lesion 3 weeks			
Sodium dichromate, 0.5%	Reapplied daily 3 days	Crusted lesion 3 weeks			
		3 days	1 week	2 weeks	3 weeks
Potassium chromate, 0.5%	8 hours a day for 3 days	3*	2	1	1
Sodium dichromate, 0.05%	8 hours a day for 3 days	2	1	0	0
Sodium dichromate, 0.005%	8 hours a day for 3 days	1	1	0	0
Zinc chromate, pure	8 hours a day for 3 days	1	0	0	0
Lead chromate, pure (insoluble)	8 hours a day for 3 days	0	0	0	0
Chromic nitrate, 10% (trivalent)	Reapplied daily 3 days	±	0	0	0

* These numbers indicate roughly the size of the ulcer and the duration of a crusted lesion. Thus "3" represents a shallow crusted lesion 2 by 4 mm. in size, "2" a lesion 1.5 by 3 mm., and "1" a lesion 1 by 2 mm. The ± indicates redness in the area of the scratch but no ulceration.

The question of preemployment patch testing is a controversial one. Such tests would not demonstrate those who will become sensitive after several months of exposure. However, it seems that in such industries as the aircraft and railroad diesel shops preemployment patch testing might be of benefit in pointing out some potential dermatitis patients and would reveal a few who could not tolerate even minimal exposure. The danger of sensitization developing from a 48 hour patch test seems rather remote, judging from the usual history of the dermatitis appearing after several weeks or months of contact. Certainly information obtained from a large series of preemployment patch tests concerning the significance of negative, questionable, and positive reactions as compared to the working exposure to chromate compounds would be very worth while. Further, more careful observations on factors of time and intensity of exposure relative to sensitization would be valuable.

---

14. Engelhardt, W. E., and Mayer, R. L., cited by Pirilä, V., and Kilpiö, O.: On Dermatoses Cased by Bichromates, Acta dermat-venereol. 29: 550, 1949.

CLINICAL CHARACTERISTICS

Morphologically chromate dermatitis varies from an acute vesicular weeping eruption, to dry, erythematous, slightly elevated squamous plaques that may be rather well circumscribed with normal skin between. Sometimes grouped papular lesions are seen. The commonest sites are the dorsum of the hands, wrists, and forearms. The neck and eyelids may be affected or any other part with which the chromate comes in contact. While there are no specific morphological characteristics, in a plant where these eruptions are frequently seen they are soon spotted as an entity.

Acute or minimal eruptions may heal in two to three weeks. The dry patchy eczematous eruptions may be very slow to heal, lasting sometimes six weeks to six months even after the patient is removed from all contact with the material. This is particularly true if the eruption is of several months' duration or if it is a second or third exposure. Chromate dermatitis often differs from the usual contact dermatitis in its patchy distribution and longer course.

TREATMENT AND PROPHYLAXIS OF *CHROMATE DERMATITIS*

Early detection of chromate dermatitis is of utmost importance if prolonged disability is to be avoided. There is apparently no "hardening" or increased tolerance of workers on further exposure to chromate, at least not after a sensitivity dermatitis has developed. On the contrary, with subsequent exposure each attack seems to be severer and more extended. As mentioned above, however, the likelihood of sensitization does not seem to increase with the duration or intensity of exposure.

Treatment should consist of wet dressings when indicated and bland local applications. In stubborn cases x-ray treatment will probably hasten healing. Dimercaprol (BAL) in a 3% ointment has been advocated for chromate dermatitis, although the evidence of its effectiveness is not very striking.[15] Injections of dimercaprol seemed to have little effect on the eruption of one patient on whom it was used.[9]

The problem of prevention or control of chromate dermatitis is of utmost importance. Where dust, mists or sprays are encountered, proper ventilation, plant cleanliness, exhaust fans, and ducts, protective clothing, and masks are indicated. Where chromate powder and solutions are used, these measures and particularly careful handling to prevent contamination of the work area are important.

Workers handling chromate should be provided with proper protective clothing such as rubber gloves and aprons when it is feasible. Facilities for immediate cleansing should be provided for workers who must come in contact with concentrated chrome compounds. Contaminated areas should be thoroughly washed down and cleansed before men work in them. Equipment should be designed to facilitate the handling and to prevent or minimize the leakage of the solutions.

The workers should be told something of the potentially harmful nature of the substance with which they are working, and the extent of the danger, which actually is not great, should be explained. Otherwise exaggerated stories of the hazard soon spread through the plant and the whole industry, for example, the stories of the so-called prime poison in the aircraft industry and diesel itch in the railroad industry. Workers should be impressed with the importance of reporting for examination at the first appearance of an eruption. It can then be determined by patch testing whether or not chromate is the offending substance. If the sensitivity is not severe, the worker may attempt to resume work with extra precautionary measures. If the dermatitis then recurs, he should immediately be removed from contact with the material.

Chrome compounds present a relatively small industrial hazard even in the industries where they are used. If the danger is recognized and suitable precautionary measures are taken, they can be safely used wherever such use is indicated.

SUMMARY

Chromium in metallic form and in its trivalent and hexavalent forms is important in many manufacturing and industrial processes. Some of these are electroplating, anodizing and other anticorrosive metal treatments, tanning of leath pigments and anticorrosive paints, mordanting of wool, fu and leather, and photoengraving and lithography.

Workers come in contact with chromates in the form mist or dust that is inhaled and in solution or solid for Inhalation may produce acute pulmonary symptoms or chron hepatic intoxication; in some rare instances of long exposu to dust, carcinoma of the lung is apparently produced. Pe foration of the lower nasal septum may result from inhal tion of mists or dust. Chrome ulcer is produced by conta of the material with an abrasion or any break in the epiderm

Dermatitis due to contact of chromate-sensitive perso with these substances is the most important of the industr hazards encountered. Apparently only the hexavalent co pounds are sensitizing. The incidence of such sensitivity a the factors influencing its production are discussed.

Chromate dermatitis is often patchy in distribution a more prolonged in its course than the usual contact dermati Prophylactic measures include protective clothing, proper signing of machinery, and industrial engineering to reduce to prevent contact with the material and contamination work areas. Education of the workers as to the nature the danger and the early detection, investigation, and mana ment of any eruption that occurs are of great importance.

MEDICAL MOTION PICTURES

NEW FILM ADDED TO A. M. A. MOTION PICTURE LIBRARY

Principles of Fracture Reduction: 16 mm., color, sound, showing t 30 minutes. Produced in 1953 by Churchill-Wexler Productions, Angeles, for the Veterans Administration. Procurable on loan (ser charge $3.00) from Committee on Medical Motion Pictures, Ameri Medical Association, 535 North Dearborn Street, Chicago 10.

This film presents first, the cardinal principles for clo reduction of fractures employing well-executed anima drawings. Then, using both patients and models, it illustra the application of these principles as they apply to the spli ing of fractures both in first aid and in treatment. The of splints, traction, and plaster of Paris is well illustrated, well as the manipulation of several simulated fractures us local anesthesia and various methods of improvised tracti to facilitate the manipulative reduction. Some of the mani lations using improvised traction are shown by model in farm house situation where it was impossible to obtain p liminary roentgenograms. Although this may at times necessary, wherever possible, manipulation and reducti should be deferred until roentgenologic study is possible. a teaching film it seems unfortunate that this point is stressed. The photography, animation, and narration are high quality. In the last section the use of the model se previously makes the film slightly less realistic and less teresting than it might have been, but this is not a serio fault. On the whole, the film is excellent and should pro of value to both medical students and practicing physicia It probably represents the best elementary film now availa on this subject.

Fred Bauer Waits: 16 mm., black and white, sound, showing time minutes. Produced in 1952 by Victor Weingarten, New York, for, a procurable on loan or purchase ($45.00) from, Health Information Found tion, 420 Lexington Ave., New York 17.

The primary purpose of this film is to convince nonmedic persons that early diagnosis and treatment of vague illne prevents considerable worry, emotional dislocation of famil feeling of insecurity in children, and prolonged treatme when diagnosis is ultimately made. The father of the fami suffers a complex of symptoms that he mistakenly thinks cancer and, because of that attempt at self-diagnosis, delays treatment until his diabetes is far enough advanced to be very troublesome to him, and very disturbing to his family. His preoccupation with the idea that he has cancer is ultimately picked up by the family, causing even the children to exhibit the insecurity associated with the possible loss of a parent. When his diabetes is discovered and when he is under adequate treatment, the family troubles disappear and normal family relationships are resumed.

The developing symptoms of diabetes are quite obvious, but, through the confusion of some of these symptoms with the keys to cancer detection, the father is led to a false diagnosis of his condition. This situation dramatically points out the dangers inherent in self diagnosis by a nonmedical person. This film would be most suitable for adult groups. With proper presentation by a well-prepared instructor, it could be used in the 11th and 12th grades. The photographic quality of this motion picture is excellent. The sound quality, however, is below average.

BUREAU OF LEGAL MEDICINE AND LEGISLATION

MEDICOLEGAL ABSTRACTS

Practice of Healing Art Not Interstate Commerce.—This was an action for damages for an alleged violation of the Sherman Anti-Trust Act. From a judgment in favor of the defendants, the plaintiff appealed to the United States court of appeals, tenth circuit.

The plaintiff, a chiropractic institution, filed a suit for damages against the medical society of the city and county of Denver; a number of present and former members of the state board of health; a number of former and present officials of the medical society; and a number of individuals, alleging, among other things, that the defendants combined and conspired to prevent the licensing of the plaintiff institution by the proper authorities of the state of Colorado to prevent the operation and maintenance of such institution and to allocate to the members of the medical profession within the state of Colorado the entire practice of the healing arts within that state, to the exclusion and restraint of the practice of chiropractic. The defendants moved to dismiss the action on the ground that it did not state a claim on which relief could be granted, and the motion was sustained, hence this appeal.

The practice of the healing arts in Colorado, including chiropractic, is wholly local in character, said the court of appeals. The alleged conspiracy and the acts alleged to have been done in furtherance thereof had for their purpose and object the monopolization and restraint of purely local activities. No price fixing or price maintenance for professional or other services was involved. There was no intent to injure, obstruct, or restrain interstate or foreign commerce. The mere fact that a fortuitous and incidental effect of such conspiracy and acts may be to reduce the number of persons who will come from other states and countries to the Spears Hospital for chiropractic treatments does not create such a relation between interstate and foreign commerce and such local activities as to make them a part of such commerce. To come within the purview of the Sherman Act, the restraint of commerce or the obstruction of commerce must be direct and substantial and not merely incidental or remote. The conspiracy or combination must be aimed or directed at the kind of restraint that the Act prohibits, or such restraint must be the natural and probable consequence of the conspiracy. Where, however, the object and purpose is to restrain or monopolize activities or matters purely local in character, those facts may be considered in determining whether the effect on interstate or foreign commerce is direct and substantial or only incidental, indirect, and remote. Here, the court said, the purpose and object of the conspiracy and of the means adopted to effectuate it were to restrain the practice of chiropractic and to allocate to the medical profession the practice of the healing arts in Colorado. It is this exclusively local aim and *not the fortuitous* and incidental effect upon interstate and foreign commerce that gives character to the conspiracy. The effect upon interstate and foreign commerce was fortuitous and remote and not direct and substantial. We conclude, therefore, *said the court,* that in the instant case there was no direct, immediate, or substantial effect on interstate or foreign commerce bringing the alleged conspiracy within the scope of the Sherman Act.

The court of appeals specifically stated, however, that it was unnecessary to pass upon the question of whether the practice of the healing arts, including chiropractic, is trade or commerce within the meaning of the Sherman Anti-Trust Act. Accordingly the judgment of the trial court sustaining the defendants' motion for dismissal was affirmed. *Spears Free Clinic and Hospital v. Cleere, et al., 197 F. (2d) 125 (1952).*

BUSINESS PRACTICE

The following material is based on a public relations manual issued by the Public Relations Department of the American Medical Association.—Ed.

ADJUSTMENT OF FEES

No person needs to go without medical care in this country because he is unable to pay for it. Every day, physicians provide care for persons who, for good reasons, are financially unable to meet their medical bills. If people complain that medical care is unavailable to those without funds, it is becaues they are unaware that each year physicians quietly and modestly give millions of dollars worth of free medical care. Many medical societies have made public their willingness to provide medical care to anyone who cannot pay for it. These programs are meeting with good public relations effects, but the task of deciding whether to reduce a fee or cancel it entirely in a hardship case falls to the doctor.

There are two prevailing philosophies on this question. One belief is that a doctor should reduce his fee but not cancel it, in order to save the patient's pride. The man who pays a small sum toward his expenses does not feel like a charity patient. The second philosophy is that a doctor should never reduce but completely cancel a fee if necessary. This evolves from the thought that a doctor should not bargain with his patients about charges. The inherent dangers in too readily reducing or canceling medical fees are that it encourages the irresponsible persons who believe the world owes them a living and it smooths the way for the cheats who dress up in shabby clothes when they come to the doctor to give the impression they are unable to pay for their medical care. Although the poverty of a patient should command the gratuitous services of a physician, it is difficult for a physician practicing in a large city to know whether a patient can pay for care. Patients must be educated to discuss their financial problems with their doctor before contracting for care.

Here are some suggestions to guide a physician in deciding whether a fee should be reduced or canceled. First, he should try to get adequate information about the patient's financial status. It is important to encourage advance fee discussions. Secondly, when a patient requests a lowered fee, he should investigate locally to learn whether the person is truly needy. If it is possible to determine if a needy patient is eligible under local and state public assistance programs, the physician can put him in contact with these groups. Thirdly, when referring patients to another physician, it is helpful to send financial information. And, finally, he should make financial arrangements that best serve the interests of the patient.

Sometimes the generosity of a physician backfires. It is dangerous to reduce a fee for an operation that the patient did not survive. This implies negligence or incompetence on the part of the physician and could form the basis for a malpractice suit. In such cases, it is better to submit a bill for the amount originally agreed on. Most patients are anxious to pay their own way. The physician often can settle the fee problem by following the directives of his heart.

THE LEISURE CORNER

MODEL RAILROADING: A FATHER-AND-SON HOBBY

As the Yuletide season approaches, many readers of the "Leisure Corner" will, as the result of ardent petitions advanced by a wide-eyed, mechanically-minded younger generation, undoubtedly find that model railroading also has an equally strong fascination for them. Interest in model scale railroading as a popular father-and-son hobby is a phenomenon based partly on a mutually shared interest that first takes root in early childhood and that later expands during adulthood. Dyed-in-the-wool participants are convinced that the hobby affords an assortment of challenges to the combined aptitudes and ingenuities of the two generations. Actually, the creation of a model railroad is an expression of ability to create, plan, and perform, and this is soon made evident in the need for painting, assembling, carving, bending, soldering, molding, drilling, and sawing. No two model railroads are similar, and that is one of the reasons why model scale railroading is a hobby with such widespread appeal to young and old alike.

The imagination of father-and-son model railroaders will channel their energies into any one of dozens of intriguing construction situations—from the building of a simple railroad to a complicated system with elaborate signals; junctions with three tracks branching out of four; lighting arrangements that produce effects of daylight and nighttime or thunderstorms and sunsets; and create brightly colored passenger trains and lengthy freight trains, which traverse make-believe countrysides interspersed with towns, valleys, and mountain ranges. Perhaps wistful memories of a childhood spent in a peaceful pre-World War I era will influence the physician-father in his decision, and, in that case, circus trains with special equipment and gay colors will fascinate the two generations of model train magnates. Again, a model railroad need not necessarily represent the latest form of twentieth century transportation; for some hobbyists, broad-stacked, brightly ornamented eight-wheeled engines with polished brass trimmings and huge headlights hold definite appeal. On the other hand, if the senior-and-junior railroaders are enchanted by rural life or teeming industrial environs, small towns, fishing villages, mountain resorts, freight yards, oil wells, quarries, or even steel mills these, too, can be incorporated in a model railroad system. The point is that model railroading permits the imagination to run riot, enabling father and son to pursue their own individual bents and, at the same time, serving up heaping doses of that contented feeling.

Model railroading provides its devotees with sugar-coated training in a half-dozen useful crafts. As most hobbyists quickly learn, newcomers will often find themselves unfamiliar with the numerous techniques characteristic of this mechanical hobby. However, they soon become proficient in drilling and tapping holes and in working with sheet metal and fragile wood; they soon learn a little about soldering and about how dies and patterns are made; something about electrical intricacies and how to differentiate a weak joint from a well-engineered joint; and how to distinguish between a well-made mechanism and a shoddy mechanism. Hobbyists will frequently be surprised to discover a newly acquired dexterity in the use of their hands, so that tasks once regarded as being impossible to perform turn out to be simple, routine matters. This, of course, is not to imply that an apprenticeship in model railroading will convert physicians and their offspring into qualified mechanical engineers; but the abilities that are acquired while in pursuit of the hobby will make its participants more useful persons to have around the house or home. At least, the wife and mother of the household may eventually find this to be the case.

Nearly all model railroads grow piecemeal, usually starting with the assembly of a rolling stock from a kit and later adding several cars and a locomotive, as the track plan takes shape in the minds of the builders. Gradually, more and more models are accumulated, first for an entire train, then for two trains. When this stage is reached, the hobby begins to multiply in its manifold possibilities, for a minimum of two trains enable hobbyists to operate train service on a model railroad in a realistic manner. And as the model railroading venture grows, there is always the strong possibility that other members of the family—and this includes mother and the younger sisters—will interest themselves in the hobby. It has been claimed that few hobbies succeed in bringing teen-agers back into the family group as effectively as model railroading; and, indeed, the most desirable scenic effects have often been created by enthusiastic mothers of the household.

In order to eliminate stooping on the part of the older hobbyists, almost all scale model railroads are now constructed away from the floor. Wood is used for the supporting frames, and track is usually laid on flat strips of wood so that it can be unscrewed at will when changes are contemplated. Scenic terrain is composed of plaster or some other moldable material spread over a lath of wire screen or cloth; buildings generally consist of wood or cardboard; locomotives are constructed of metal; and cars are made either of metal, wood, or plastic. The trend among model railroad hobbyists is to build cars and engines from kits that contain every construction part required. Recent growth of interest in scale model railroads is partly indebted to the toy train field. Scale modelers speak of toy trains as "tinplate," many model rail systems being derived from a Lionel, American Flyer, or Marx Christmas train set. In reality, scale model railroading is not as suitable a hobby for very young boys as is the tinplate train, but as the youngsters become teen-agers, the skills and crafts associated with scale model railroading provide a distinct advantage.

The principal difference between finished tinplate and scale equipment lies in the track. Tinplate track is constructed in sections that can easily be taken apart; on the other hand, in scale track the proportions are more accurate, the curves are broader, and the track can be made to serve in a more permanent form. Tinplate passenger trains are built to be undersized and short, so that they can readily traverse the sharp curves inherent in sectional track. Tinplate trains employ a sequence reverse, and the motors operate on alternating current derived from a transformer. Scale trains utilize an improved reverse scheme that depends on direct current coming from a power pack. A transformer cannot be used unless a rectifier is employed to convert it into a power pack. Scale model railroads usually have two running rails for electric power distribution. When a third rail is desired, scale model railroaders locate it to either side of the track. Although track is very easy to lay, the beginner can be fooled. It is therefore a good idea to first build a small test yard before commencing construction of a more permanent type of railroad system. In model railroading it is important to have every part of the model railroad truly proportional to every other part. Passenger cars on a real railroad are generally twice as long as box cars, as they are in properly proportioned scale railroads.

Today there are four scales for which a variety of equipment is available. Model railroaders usually identify them by letter for each gauge of track—O, S, HO, and TT. Gauge is defined as the distance between inside rail faces of the track; standard gauge is 4 ft. 8½ in., and, in modeling standard gauge equipment, the scale should properly relate the track and cars. Scale is the ratio of size the models bear to the original and is usually stated in terms of fractions of inches or millimeters in the model to 1 foot in the original. Gauge O has proved to be the favorite type of gauge for many hobbyists who want detail in cars and locomotives. HO gauge is about half the size of O gauge, and OO is a little more than half the size of HO. O gauge cars cost approximately twice as much as HO equipment; engines range anywhere from 25% to 75% more in price. If there is any uncertainty about which gauge is best to buy, it might be well to experiment with a car kit and a limited amount of track material in each gauge. When the cars and track are assembled, it is soon possible to obtain a clear notion about construction preferences. Once this is determined, model scale railroading is well on its way to becoming an enjoyable, lifelong hobby.

Intravenous Anesthesia for Obstetrical Delivery.—Thiopental (Pentothal) sodium intravenously, combined with procaine infiltration of the abdominal wall, was used as method of anesthesia in 90 cases of cesarean section. There were no maternal deaths. The effect on the infant was minimal. Most of the babies breathed as soon as the nose and mouth were cleared by suction. Oxygen under pressure was used in a few cases in which there was some depression of the baby's respiration. The same type of anesthesia was employed in 179 women for ligation of the fallopian tubes in the puerperium as a method of sterilization. Thiopental sodium was used as the anesthetic agent for 473 patients who underwent minor procedures, such as curettage of the uterus, incision and drainage of abscess of Bartholin's gland, removal of secundines, and biopsy and cauterization of the cervix. Thiopental sodium is satisfactory for short procedures. In combination with procaine infiltration of the abdominal wall, thiopental is an effective anesthetic for cesarean section and puerperal sterilization. Pentobarbital (Nembutal) sodium in combination with meperidine (Demerol) hydrochloride and scopolamine (Hyoscine) was used for vaginal delivery in 6,257 patients; 100 mg. of meperidine and 0.6 mg. of scopolamine intramuscularly in combination with 200 mg. of pentobarbital sodium orally were given as soon as the patient's labor became uncomfortable, with little regard to cervical dilatation. Pentobarbital sodium was given intravenously when the previous procedure was no longer sufficient to make the patient comfortable. Pentobarbital sodium was supplemented by scopolamine in 0.3 mg. doses intramuscularly each two to three hours as indicated, and by a second or third intravenous injection of pentobarbital sodium varying from 200 to 350 mg., depending on the patient's response. Additional anesthesia was generally needed when the cervix was fully dilated. This was obtained by additional pentobarbital sodium intravenously, or by additional meperidine hydrochloride intravenously in doses of 100 mg. The author was more inclined to use meperidine hydrochloride than additional pentobarbital sodium for delivery, if the total dose of pentobarbital sodium was near 1,000 mg. Pentobarbital sodium intravenously combined with scopolamine, meperidine hydrochloride, and pudendal nerve block proved to be an effective way of controlling pain for vaginal delivery. The use of pentobarbital sodium seems to be contraindicated in patients in whom there is any impaired function of the liver. There is no one intravenous anesthetic agent that is entirely satisfactory in obstetrics; but by combining several drugs and varying the dosage it is possible to obtain satisfactory analgesia and anesthesia for the first and second stages of labor without unduly affecting the baby.

Pheochromocytoma.—A case of bilateral, malignant pheochromocytoma with hypertension is described in a 9-year-old Negro boy. Severe constipation was the outstanding symptom. *It was so severe that it was impossible to perform any of the* tests for detection of a pheochromocytoma. The constipation ultimately produced all the signs and symptoms of intestinal obstruction. Enemas gave poor results but produced an outpouring of epinephrine which increased the constipation as well as the strain on the heart and this eventually led to congestive heart failure. Weakness and sweating were prominent symptoms. The presenting symptoms were varied in 14 other cases of pheochromocytoma in children collected from the literature. Excessive sweating was prominent in nine patients. Severe constipation was not described in any of the *14 patients, and paroxysmal hypertension was described in* only one. Pheochromocytoma should be considered in the differential diagnosis in all cases of hypertension in both children and adults.

Arterenol Treatment of Shock.—In cases of shock, blood pressure must be raised before vital organs are damaged by lack of adequate perfusion; administration of fluids is often not adequate to this, and thus cases of "irreversible shock" arise.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individual subscribers, provided they reside in continental United States or Canada. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover only the last 11 years, and no photoduplication services are available. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Arterenol is a drug closely related to epinephrine, differing only in the absence of the N-methyl group but having different pharmacological properties in that it is primarily a peripheral vasoconstrictor and has only a minimal stimulant effect on the heart. It is of value in the treatment of shock because (1) it raises blood pressure rapidly, regardless of the cause of hypotension, (2) its effects are easily controlled for obtaining any desired blood pressure response, (3) it is a short-acting agent, and thus avoids the danger of excessive elevation of blood pressure, and (4) its side-effects are minimal. The authors observed the action of the drug in 25 normotensive patients, and in 44 patients in shock, including 14 with myocardial infarction, 9 with overwhelming infection, 6 with excessive hypotension secondary to medication, and 15 in surgical shock. All of the last group had previously failed to respond to adequate fluid replacement and blood transfusions. Results were encouraging: in only two patients of the 44 did the blood pressure fail to rise to normal with arterenol, and 24 patients recovered completely. It was not always possible to reverse postoperative "irreversible shock." The drug proved most useful in severe hypotensive states following the administration of certain drugs to excessively sensitive persons.

Nonspecificity of Electrocardiogram in Coronary Disease.—The shortcomings of electrocardiography are pointed out with a view toward emphasizing caution in interpreting findings and the importance of checking these against clinical evidence. Changes in the T-wave, in the RS-T segment, and in the QRS complex of the electrocardiogram generally reflect, respectively, myocardial ischemia, current of injury, or death of muscle. The T-wave, the most labile and least specific feature of the electrocardiogram, may be affected by a large variety of factors, only one of which is ischemia. Changes in the RS-T segment usually but not always correspond to acute muscle damage. It is generally transitory and rarely permanent. Like the T-wave this may indicate an anatomical or biochemical lesion. QRS changes practically always signify death or replacement of the heart muscle; this is generally associated with coronary artery disease. Rarely it may result from heart muscle damage from other causes. The electrocardiogram is quite accurate in the detection of acute myocardial infarction but inaccurate in the diagnosis of old or of multiple infarcts. It remains to be seen whether the newer vectorcardiography will attain a greater accuracy.

Surgical Significance of Tumors in Identical Twins.—This report of sympathicoblastoma in monozygous twins is believed to be the first. A review of the literature shows that tumors that have been common to both monozygous twins are chondrous exostoses, medulloblastoma, glioma, adenofibroma and carcinoma of the breast, melanoma and retinoblastoma of the eye, congenital cystic tumors of the kidney, papilloma of the larynx, carcinoma and cystoma of the ovary, nevi of t skin, testicular sarcoma, and myoma and adenocarcinoma the uterus. Of identical twin boys born July 29, 1951, tw B underwent surgical removal of a sympathicoblastoma the region of the left kidney on Dec. 12, 1951. Laparoto was advised for his brother, but refused by the moth Roentgenotherapy did not improve the disease in twin whose condition deteriorated rapidly until his death on Mar 10, 1952. Meanwhile, twin A, in whom a metastatic lesi had developed in the right temporal region, underwent exploratory laparotomy on Jan. 24, 1952. A biopsy from t right temporal mass was taken at the same time. The li was found to be infiltrated by metastases in both the ri and left lobes. The primary tumor was in the right adre with extension into the kidney and the roots of the mesenteri Twin A was not treated with roentgenotherapy, but w triethylene melamine, 1 mg. daily for three days. Later, the age of 15 months, an apparently spontaneous remiss occurred, but there remained several metastatic lesions, so of which were similar to those found in his brother at autop The recognition of a tumor in one of a pair of identical tw should make the clinician alert to the possibility of a tu in the other twin. In general, when the tumor is discove in one twin during infancy or early childhood, the likelih of concurrence is probably even greater than it is in adu since the genetic factors are more likely to predomin Although vigilance with respect to the apparently healthy t is to be recommended at any age, it is especially import in the tumors of early life.

Management of Carcinoma of Lung.—Although surgical te niques have been greatly improved, the present yearly salv of cases of carcinoma of the lung is barely 5%; this is to the inadequacy of present diagnostic methods. Two-thi to three-fourths of all patients are inoperable when first s There has been a steady increase in the incidence of disease within the last 17 years, and it is on its way to coming the most frequent type of malignant lesion in m It is suggested that physicians should keep a close watch men over 40 who complain of respiratory symptoms that they refrain from relieving such symptoms without finding out what is wrong with their patients, since a ma cause of the high mortality rate of carcinoma of the l is the relief of its symptoms by sulfonamides and, particula antibiotics. Cardiac, psychosomatic, and other diseases frequently accepted as causes of respiratory symptoms are really caused by carcinoma of the lung, or, if no diagn can be made, the patient is subjected to observation w actually an exploratory thoracotomy should be perform Of the 235 patients to whom carcinoma of the lung pro fatal at the Charity Hospital of New Orleans between 1 and 1952, 76 had typical histories, 98 more or less sugg tive ones, 53 entirely atypical ones, and the remaining 8 d too soon for any information to be obtained. Diagno methods in carcinoma of the lung can be improved, parti larly by a more careful study of roentgenograms taken f tuitously or for other reasons. We rely chiefly, at the pres time in the diagnosis of the early, resectable case, on prompt and bold resort to exploratory thoracotomy, on j tifiable evidence if it exists or on simple clinical suspic if it does not. Both internists and surgeons must display greater boldness than they have in the past if lives are to saved in carcinoma of the lung.

Gastroscopic Diagnosis of Gastric Ulcers.—This report is based on gastroscopic studies in 333 patients with gastric ulcers in whom a differentiation had to be made between a benign and a malignant lesion. Since adequate follow-up was not possible in 60 of these cases, there remain 273 cases in which the gastroscopic diagnosis could be verified. A sharply cut-out edge and the presence of small hemorrhages in the normal mucosa were considered gastroscopic signs of benign ulcer, whereas blending of the edge of the ulcer, bleeding at the edge, small ulcerations in the vicinity of the ulcer, and dark red color of the ulcer wall were regarded as indicative of malignant disease. A total of 239 cases were correctly identified by gastroscopy, that is, 191 as benign ulcers and 48 as malignant ulcers. A wrong diagnosis was made in 20 cases: 18 benign ulcers were considered malignant and two malignant ulcers were considered benign. In 14 cases the gastroscopist was not able to commit himself, chiefly because a portion of the ulcer could not be visualized. Of these, nine proved to be benign and five malignant. None of the usual gastroscopic signs for the differential diagnosis of benign and malignant ulcer seems to be entirely reliable. Occasionally there may be an "unsharp" edge in a benign ulcer or a sharp edge in a malignant one; therefore, the clinician can accept the gastroscopic impressions only as suggestions that he has to correlate with other clinical data. There are cases in which both the roentgenologic and the gastroscopic diagnosis are wrong. If other diagnostic procedures such as gastric analysis, Papanicolaou test, stool examination for blood, sedimentation rate and clinical observation, are employed, the clinician can still arrive at the correct diagnosis. The author concludes that the percentage of correct gastroscopic diagnoses is so high that it appears to be a valuable or even the most valuable method in the differential diagnosis of gastric ulcer. Gastroscopic observation has been known to establish a correct differential diagnosis of gastric ulcer when this proved impossible with the inspection of the gross specimen. This is due to the circulating blood producing more brilliant coloring.

Giant Benign Gastric Ulcers.—Marshak and associates present the histories of seven patients with giant gastric ulcers, the diameter of the lesions ranging from 3.5 to 7 cm. The average age of onset was 60 years, the youngest patient was 50 and the oldest 74. Clinically, the chief complaint was abdominal pain, not responding to strict ulcer regime. Progress of the patient, as followed by roentgenograms, failed to reveal any evidence of healing of the gastric lesion. Because of these factors the clinical impression was malignant disease. On roentgen examination, all these giant ulcers were visualized on the posterior wall near the lesser curvature in the midcorpus of the stomach. The roentgenograms suggested a benign lesion in four cases and carcinoma in one; the other two were equivocal. Gastroscopic examination suggested a benign lesion in two out of four lesions. Gastroscopically, the ulcers presented smooth, regular, well-defined margins, but the bases were necrotic. Gastric acidity was normal or elevated. Melena was present in one, in another the stool gave a positive guaiac test, while in the others the guaiac test was negative. At laparotomy, a hard, indurated mass involving the stomach, pancreas, and occasionally the liver or mesentery was found. The surgeon in some instances was reluctant to resect the stomach because the huge, indurated mass suggested an extension of the malignant process into adjacent tissues. The characteristic pathological change was a complete, walled-off perforation through the entire thickness of the gastric wall. The base of the ulcer was formed by the capsule of the pancreas or liver. Microscopic examination of the lesion, however, revealed chronic, benign, gastric ulcer. It is doubtful whether these giant, benign, perforated, walled-off gastric ulcers ever heal completely under medical therapy. The surgeon must be aware of this clinical entity, since gastric resection results in a cure.

Hyaluronidase in Traumatic Surgery.—Collections of extracellular fluid in the form of hematoma, hemarthrosis, and edema complicate many cases seen in orthopedic and traumatic surgery. Definitive treatment is often delayed while the surgeon waits for nature to dispose of hematoma and edema. The enzyme hyaluronidase is now available as a means to accelerate the dispersion of these fluids. Two years' experiences with this enzyme at the New York Orthopedic Hospital are reviewed in this report. Hyaluronidase acts by the depolymerization of the mucopolysaccharide hyaluronic acid. This acid forms the main constituent of connective tissue and joint fluid. The breakdown of these natural barriers facilitates rapid dispersion of extracellular fluid collections. The sprained ankle demonstrates the advantage of hyaluronidase therapy. The area of maximum swelling and its periphery are injected with 1,000 turbidity reduction units of the enzyme in 5 cc. of 1% procaine; an elastic bandage is applied and the patient is allowed to walk. One or two hours later, the swelling and hematoma are greatly reduced. The elastic bandage is then reapplied. By allowance of immediate painless weight-bearing, the disability time is greatly reduced. The efficacy of local anesthesia can be increased by the use of hyaluronidase, particularly in fractures about the forearm. Usually there is a 20 minute lag between injection and adequate anesthesia. By the addition of 500 turbidity reduction units of hyaluronidase to the procaine solution, excellent anesthesia is obtained in three to four minutes. Application of an elastic bandage enhances the action of the hyaluronidase in dissipating the hemorrhage and edema. With complete anesthesia and the reduction of the surrounding swelling, the bone ends are more easily palpated and a satisfactory reduction is possible. Hyaluronidase and procaine offer an effective nonoperative method to relieve the subfascial tension caused by edema and hemorrhage in supracondylar fractures of the elbow, which involve the threat of Volkmann's contracture. A case history is presented to illustrate this. Soft tissue hemorrhage, postoperative hematoma, and hemophylic hemarthrosis were other conditions in which hyaluronidase proved helpful. In a hemophiliac patient with an acute hemarthrosis, the clotting time and other laboratory data are obtained. Plasma or fresh blood is given to lower the clotting time. The joint is entered with a small bore needle, and 3 to 4 cc. of the viscid blood is removed. Then 1,000 turbidity reduction units of hyaluronidase are mixed with procaine in the amount equal to that of the blood withdrawn. This is injected into the joint and a snug elastic bandage is applied. No treatment other than bed rest is necessary. When the patient is reexamined in 24 hours, pain is usually absent and the range of motion is much greater. Occasionally, a second injection is necessary. After 48 hours, the patient can walk without pain or has free use of an upper extremity. This method produced favorable results in 19 of 20 cases of hemarthrosis.

Osteitis Pubis of Traumatic Etiology.—A review of the literature indicates that osteitis pubis is an inflammatory disease of bacterial origin that occurs most commonly following retropubic surgery in males. A youth with osteitis pubis was recently studied in the orthopedic surgery department of the University of Illinois hospitals. The uniqueness of this case and the review of four other very similar cases in the literature suggested that an entity similar to postoperative osteitis pubis in the elderly male may also occur in the younger age group. A youth, aged 18, was hospitalized with a history of lower midabdominal pain with radiation into the upper medial portions of the thighs. The onset had occurred one year previously while running in indoor track at high school. In January, 1949, his physician, suspecting appendicitis, removed the appendix, but upon resuming physical exertion the patient experienced a return of discomfort. The pain troubled him when he ran or walked, and he had a "waddling" gait when fatigued. In January, 1950, roentgenograms revealed a destructive lesion in the symphysis pubis. A biopsy was done, and a diagnosis of chondrosarcoma was made. The patient was then referred to the University of Illinois hospitals. Bony enlargement of the symphysis pubis was noted. Passive abduction of the hip joints beyond 20 degrees produced severe pain in the adductor groups and the symphysis pubis. In March, 1950, with a clinical diagnosis of chondritis of the symphysis pubis, a suprapubic resection of this structure was accomplished, the defect being bridged by an autogenous tibial-bone graft. At the time of surgery, the lesion appeared yellow in color, was firm and gritty in consistency, and contained irregularly arranged bony spicules. The suprapubic wound failed to heal, and within 10 days gross infection was evident. A hemolytic strain of Micrococcus pyogenes var. aureus (Staphylococcus aureus) was cultured from the pus. Neither penicillin nor streptomycin controlled the infection. Two months after its insertion, the bone graft and a sinus tract that communicated with the skin were removed surgically and the wound was packed open. Healing then occurred without sinus formation, and the patient was ambulatory six weeks later. He subsequently returned to full activity, including strenuous sports, without complaint or disability. A specimen for histological examination made possible a description of the pathological changes associated with osteitis pubis of traumatic origin in a young person. These findings suggest that the traumatic disease was inflammatory in nature and possibly bacterial in origin. Four similar cases from the literature are reviewed. Osteitis pubis of traumatic origin should be treated conservatively. Complete bed rest may be necessary in the acute phase and a plaster-of-Paris spica may be reuired to limit hip and pelvic motion in such instances. Later, ith improvement, a snugly drawn sacroiliac belt might be ieful to decrease symphysial movement during weight-bearg. Ambulation should be resumed as soon as it can be lerated, but strenuous activities should be minimized until entgenographic and clinical signs indicate healing. The adinistration of antibiotics would probably be of value during e acute phase, especially if signs of gross infection become anifest. When abscess formation occurs incision and drainge should be done.

Resection of Acquired Coarctation.—The coarctation commonly treated by surgery occurs as a congenital anomaly immediately below the origin of the left subclavian artery. In the case reported, a coarctation that was thought to be acquired was located 6 cm. above the diaphragm. While surgical repair of coarctation occurring in the usual site is no longer considered rare, only five operations have been performed and reported in patients with stenosis just above the diaphragm. In a 23-year-old woman with a long coarctation of the low thoracic aorta, a 9 cm. segment was excised and replaced by an 8 cm. preserved aortic homograft. An obliterated left subclavian artery was found. A left hemothorax occurring on the fourth postoperative day was believed to be due to a leak from an aortic fracture caused by the proximal aortic clamp. The end-result was quite satisfactory, with complete resolution of the hemothorax and normal brachial blood pressure and blood flow to distal extremities. The character and site of the lesion, as well as the medical history, support the theory that the coarctation was acquired.

Closure of Interauricular Septal Defects.—This new and successful method for the closure of interauricular septal defects is an elaboration of the one described by Söndergaard in 1952. A groove is made between the superior vena cava and pulmonary veins. With a finger inserted in the auricle through the right auricular appendage, a needle is guided subendocardially in the septal plane. It is introduced through the right auricular wall close to the root of the aorta just behind the right coronary artery. The needle follows the aorta down and through the upper portion of the interventricular septum. Through the posterior portion of the interventricular septum the needle should come more toward the left side and then out through the left auricular wall behind the inferior vena cava, close to the annulus fibrosus. The two ends of the suture are tied in the groove. This method seems to be applicable even in patients with a very large interauricular septal defect without a septal rim.

Massive Melena.—Of 4,377 patients admitted to the surgical services of the Charity Hospital at New Orleans for acute abdominal complaints, 380 (8.7%) were emergency admissions for sudden hemorrhage from the gastrointestinal tract. Of the latter group, 251 patients (66%) had hematemesis with or without melena; 129 (34%) had melena alone. These 129 cases form the basis of this report. From observations on these patients a procedure was evolved which is now followed when a patient presents himself with a story of bleeding from the rectum. First the constitutional effect of the hemorrhage, that is, the blood pressure and evidence of shock are ascertained. Blood transfusions are instituted if shock exists. A digital examination of the rectum determines whether blood is present there. If the cause of hemorrhage is not obvious, a Levine tube is inserted into the stomach to determine whether blood can be found in the upper gastrointestinal tract. Physical examination is limited to a superficial examination of the heart and lungs, measurement of blood pressure, and palpation and auscultation of the abdomen. Leukemia should be looked for. A red blood cell count and a hematocrit will indicate roughly the amount of blood loss. A nonprotein nitrogen or a blood urea nitrogen determination is made for evidence of uremia. These tests are likely to show high values in the presence of large quantities of blood in the gastrointestinal tract; however, they are not usually high enough to confuse the diagnosis with that of true uremia. If the evidence points to bleeding from the upper gastrointestinal tract, x-ray studies of the gastroduodenal segment should be considered, even during the bleeding period. Until recently the authors avoided such examinations, but they have real value, although the gastrointestinal tract containing blood clots may not give clear pictures. If the evidence points to a lesion below the gastroduodenal segment, sigmoidoscopic examination should be done. A barium enema should be given, if none of these examinations demonstrate the location of the bleeding. Massive bleeding from the rectum is not characteristic of carcinoma, the lesion is more likely to be diverticulosis and diverticulitis. It may be wise to defer the examination by barium enema if evidence of acute diverticulitis is present. Surgery may be necessary if the diagnosis cannot be established by other means, although it is unreliable for determining the location of gastrointestinal bleeding. Roentgen examination is the best method for locating lesions that cause melena, especially in the gastroduodenal segment. It is almost equally valuable in the colon above the rectosigmoid junction. Most lesions that are readily demonstrable by roentgenograms in the colon do not usually produce gross hemorrhage. Proctoscopic examination, or rather sigmoidoscopic examination, is practically infallible in lesions of the rectum and rectosigmoid junction.

Heart Disease in Chronic Arsenic Poisoning.—Robbins presents the histories of two patients with chronic arsenic poisoning. The first patient, a cotton farmer, gave a history of having dusted cotton repeatedly from 1923 through 1939 with a compound that contained arsenic, and during those years he had recurrent episodes of vertigo, weakness, nausea, and vomiting. In 1946, he again was briefly exposed to arsenic, and these symptoms recurred and were followed by sore throat, hoarseness, swelling of the face and neck, and paroxysmal dyspnea. Edema of the soft palate and of the pharynx was discovered, and although diphtheria organisms could not be found, he was treated with digitalis, pencillin, and diphtheria antitoxin. An x-ray film of the chest revealed pulmonary congestion. From 1947 through 1952, the patient was hospitalized 19 times, but he never fully recovered from the episode in 1946. Serial electrocardiograms showed myocardial disease. The second patient was a 40-year-old laborer, whose job required that he clean oil-well drilling equipment. He would mix a powder with water, place this solution in a closed container, light a fire under it, and expose the tools to the steam, previously treated with a compound of hydrochloric acid and arsenic. After having been thus employed for about eight months, he noted nausea, vomiting, anorexia, giddiness, and excessive salivation. Two months later an erythematous eruption developed about the hands and feet, associated with paresthesia. The rash spread until it involved his entire body. Conjunctival erythema and lacrimation developed. In May, 1949, he was found to have a generalized scaling pigmented maculopapular rash, with marked thickening of the palms and soles. A Kolmer blood test for syphilis was positive. In September, 1950, the burning pains in the feet had gotten worse until he could no longer stand or walk. He again had nausea, vomiting and abdominal distress. His gums were swollen painful, and his teeth loose. The hair and nails were fc to contain 33.9 parts per million of arsenic, and 24 hour u specimen contained 0.006 parts per million of arsenic. Ti ment consisted of bed rest, penicillin, and dimercaprol. T was slight improvement in the paresthesia and the cardiac diminished. He was discharged with the diagnosis of chr arsenical intoxication. In October, 1951, he was hospita because of recurrence of all symptoms, after having retu to his old job. He received dimercaprol together with a caloric diet and multiple vitamins, but his clinical resp was not gratifying. He was again hospitalized in March, 1 because of ascites, pedal edema, abdominal cramps, diar chronic cough, exertional dyspnea, and palpitations. He sponded fairly well to digitalis, low sodium diet, and merc diuretics. He was followed in the outpatient clinic, an months later symptoms of chronic congestive failure persi The etiology of the heart disease in these men was n explained. Neither patient had hypertension, retinopathy, evidence of valvular pathology; both had congestive r than anginal failure. Although in one patient the sero tests for syphilis were positive, the absence of clinical radiographic evidence of valvular and aortitic lesions cluded the diagnosis of syphilitic heart disease. The phary edema, which suggested diphtheria, was the most classic s tom of early chronic arsenical intoxication.

Gastric Decompensation.—According to Gibb there are tain aspects of prolonged duodenal ulcer that are not cl explainable by the usually accepted concepts of the mecha involved. It is usually assumed under these circumstances the lumen of the pylorus is occluded by scarring and cor tion, by edema associated with an antral gastritis or denitis, spasm, or combinations of all three. The fact retention can be relieved in most cases by bed rest, spasmodics, diet, and repeated gastric lavage leads to conclusion that edema is largely responsible. The autho amined with the flexible gastroscope the stomachs of r persons with varying degrees of gastric retention, and, e for some with maligiant lesions, he has yet to see a s pylorus that was actually stenosed or occluded or an an that was edematous to a degree sufficient to produce occlu Before presenting his somewhat different concept of the p physiological mechanism of pyloric obstruction and prolo gastric retention, he presents his idea of the normal func ing of the stomach and duodenum. In cases of repeated ul tions at the duodenal cap more and more scar tissue f and gradually the cap loses its normal elasticity. The i duodenal pressure regulatory mechanism fails, and, when pylorus opens after systole, an abnormal amount of r occurs. In addition, the lumen of the very first portion of duodenum is reduced because of scar tissue. Greater for required to get the usual amount of material through it in usual length of time. The same situation may be said to as in a stenosed and incompetent heart valve. Similar to heart, the stomach has to work harder in order to keep with its full work load. Unlike the heart, however, the st ach has no capacity to hypertrophy to assist it in remai competent. If at this point the work load of the stomac decreased, as, for example, when the patient goes on a untary or prescribed diet that reduces the quantity and cha the character and consistency of the food he eats, the stom may be able to maintain its compensation and empty in prescribed length of time. The clinical picture of pyloric s osis is not due to actual closure of the pylorus, but ra to a relative incompetence of its valve action. Because competence of the mechanism can be restored by such sin means as repeated gastric lavage does not mean that underlying pathological condition causing the situation has in any way been changed. This concept may explain why pyloroplasty does not always work as well as might be expected. The author admits that the evidence to support his concept of gastric compensation and decompensation is fragmentary, open to criticism, and may be incorrect. He feels, however, that it is a more workable theory than any that are described in the standard textbooks.

Maintenance Management of Addison's Disease.—An attempt was made to improve the administration of desoxycorticosterone acetate (DCA) in the maintenance therapy of Addison's disease, with a view toward long-term management. Formerly, the two methods of administration were daily injection in an oil solution and annual or semiannual implantation of the crystalline hormone in the form of pellets. The latter method was designed for long-term therapy, but was found technically impractical. The successful use by injection of suspensions of crystalline sex hormones, which are absorbed slowly and thus give a prolonged effect suggested to Meier, Gasche, and Frey that crystalline desoxycorticosterone acetate might be used in a similar manner. A test of this idea was run on 10 patients with Addison's disease, after the above authors' experiments on dogs and rats whose adrenals had been removed had proved successful. The maintenance treatment was carried out successfully with aqueous suspensions of microcystalline desoxycorticosterone trimethylacetate and phenylacetate given in injections of 50 to 120 mg. at intervals of four to six weeks. All of the patients received small daily supplements of sodium chloride, and two patients were also given cortisone acetate.

Peptic Ulcer.—According to Wangensteen, peptic ulcer is still a challenging problem. Patients who get along well on medical management are not candidates for surgery. The patient to whom the monotony of the ulcer diet does not appeal, the patient who is never long wholly free from pain, the patient with recurrent gastric hemorrhage, as well as the patient with periodic episode of obstruction—all should be advised to have an operation for the relief of peptic ulcer. There seems to be no reason to withhold operation from patients who have had more than one episode of hematemesis from peptic ulcer. When the medical profession learns to manage the threat of hemorrhage from peptic ulcer in a satisfactory manner, the mortality will disappear. The serious threat of perforation is now largely under control. Through improved surgical care, including employment of antibiotics and better toilet of the peritoneal cavity at the time of the closure of the perforation, the mortality of perforation is no longer as serious as it was a decade ago. Earlier and more frequent recourse to operation is particularly advisable for gastric ulcers, inasmuch as they frequently recur at the same site and involve the threat of cancer. The author concludes that the key to the reduction of the high mortality of peptic ulcer in patients between 40 and 70 is readier recourse to operation in patients who have had gastric hemorrhage, which must be recognized as synonymous with failure of adequate control by conservative means. Hemorrhage is the most important single cause of death from peptic ulcer.

Toxoplasmosis.—Toxoplasmosis has been recognized for about 50 years, and an increasing number of cases of it in humans is being reported. The authors report two new cases of congenital toxoplasmosis, one of which closely resembled erythroblastosis fetalis. It is suspected that the infection was transferred to the mother by a dog. Involvement of the placenta was demonstrated in the second case. A classification of the disease is set up which includes six types: (1) asymptomatic infection, (2) mild grippe-like infection, (3) infections simulating infectious mononucleosis, (4) chorioretinitis, (5) acquired systemic infection, and (6) congenital infection. Serologic tests such as the Sabin-Feldman dye test are used to increase and improve the diagnosis of toxoplasmosis, but effective treatment of toxoplasma infections is still needed.

Bronchogenic Carcinoma Simulating Virus Pneumonia.—Custer and Klassen show that bronchogenic carcinoma may at first produce bronchial stenosis and partial occlusion with associated pneumonia peripherally, which will respond temporarily to antibiotic therapy. However, as the cancer grows the bronchus becomes completely obstructed, resulting in recurrent pneumonitis or atelectasis which is mistaken for pneumonia. This is the type which is erroneously diagnosed as recurrent or virus pneumonia. Three case histories are presented which show the danger of making a diagnosis of virus or recurrent pneumonia. The first of these patients was treated for pneumonia by several physicians over a period of nine months. His history was compatible with, but not diagnostic of, pulmonary cancer. The correct diagnosis was not established. The second case is of interest because the history, the physical examination, and an extensive diagnostic search gave no indication of bronchogenic carcinoma. This case also demonstrates that occasionally it is extremely difficult to diagnose the cancer grossly even when the surgeon has the lung exposed. In the presence of diffuse inflammatory necrosis the frozen section reports are often misleading and the decision rests entirely with the judgment and experience of the thoracic surgeon. The third patient had had signs of a pulmonary lesion for many years and progressive symptoms with repeated bouts of pneumonia for over a year. A pulmonary malignancy was not considered until the bronchus had been completely occluded. This case demonstrates the fatality of procrastination. The authors stress that any patient with peumonia who does not respond to antibiotic therapy within three weeks should be suspected of having either a Friedlander pneumonia, lung abscess, tuberculosis, or bronchial obstruction. All efforts should be made to arrive at the correct diagnosis as early as possible, and any patient in whom bronchogenic carcinoma cannot be excluded by other means is entitled to an exploratory thoracotomy.

Poisoning Due to Anticholinesterase.—Three cases of poisoning that resulted from anticholinesterase insecticides are described in men between the ages of 18 and 37. Two of the patients were employed by a chemical plant and had been exposed to tetraethylpyrophosphate. Both these men had constricted fields of vision and inspiratory and expiratory wheezes over both lung fields. Although the patients wore full protective equipment, observed the safety rules, and did not knowingly come in direct contact with tetraethylpyrophosphate, the authors felt that their symptoms were undoubtedly due to poisoning with this insecticide. The patients were given 1 mg. of atropine subcutaneously on admission, and after two hours this dose was repeated. Elixir of terpin hydrate was given for the cough. All the symptoms subsided within a few hours. No symptoms had reappeared within 24 hours, and the patients were discharged improved. The early recognition of tetraethylpyrophosphate poisoning and prompt treatment resulted in only minor morbidity. The third patient, a farmer, had sprayed tobacco with parathion for four hours. Within one hour he complained of muscle cramps, nausea, sweating, and cough. Shortly afterward he became irrational. He was given 1 mg. of atropine subcutaneously twice on the way to the hospital and was admitted in a semicomatose state. The history revealed that the patient had sprayed tobacco with parathion for a period of about four hours two weeks previously. His only protection against parathion on both occasions was a handkerchief tied over his nose. During the first two hours in the hospital he received 12.2 mg. of atropine without signs or symptoms of toxicity; following subsequent administrations, he became restless and that was attributed to stimulation of the central nervous system by atropine. This undesired side-effect was controlled with phenobarbital sodium, and the dose of atropine was regulated according to the size and reaction of the pupils and flushing of the skin. The patient was given 0.5 gm. of dihydrostreptomycin and 400,000 units of procaine penicillin every 12 hours prophylactically for the first six days of his hospital stay in order to guard against pulmonary infection. After regaining consciousness 72 hours after admission, the patient had no recurrence of previous symptoms and no new symptoms during the following five days of observation. The mechanism of action of the tetraethylpyrophosphate and parathion is by irreversible combination with cholinesterase in all tissues of the body resulting in an excess of acetylcholine, with symptoms depending quantitatively on the amount of cholinesterase inhibited. The danger of additive toxic effects from repeated exposures to small amounts of these insecticides is stressed because of the slow rate of restoration of cholinesterase activity to normal levels. Safety recommendations for workers handling the anticholinesterase insecticide are listed.

Intravascular Hemolysis.—Two fatal cases of thrombotic, thrombocytopenic purpura are reported in a 22-year-old man and in a 62-year-old woman. In the man the disease was of relatively long duration, representing the chronic type, while the woman had the acute type of the disease. Necropsy revealed extensive thromboses in the myocardial vessels of both patients. In both cases, appreciable numbers of erythrocyte fragments were observed at the site of the changes in the myocardial vessels, varying from barely visible granules taking a positive stain for hemoglobin to cells about half the diameter of a red cell. The kidney of the woman, which had many thrombi, showed many of these cell fragments, while in the man there were neither renal thrombi nor erythrocyte fragments. These tiny cell fragments, which often had the full hemoglobin content of a normal erythrocyte, must have arisen by fragmentation of larger cells without loss of the pigment. The term schizocytes has been coined in 1892 by Ehrlich for these small red cells; they were counted by the authors in 40 consecutive suitable unselected necropsies. Organs examined were heart, lung, liver, spleen, pancreas, adrenal, and kidney. The myocardium contained the highest number in 23 cases and the second highest in 2. The kidney was highest in three, and second highest in seven. The authors believe that the myocardial vessels may be a prominent site of mechanical red cell destruction by fragmentation, thus ascribing a new functional role to the coronary circulation. The anemia in thrombotic, thrombocytopenic purpura may be caused by mechanical red cell destruction, especially at the site of vascular lesions.

Bilateral Total Adrenalectomy in Carcinoma of Prostate.—Removal of the adrenal glands, which are known to be responsible for five-eighths of the output of androgens, is an antiandrogenic measure and like other antiandrogenic measures (orchiectomy and estrogen therapy) it has a beneficial effect in metastatic disease of the prostate. Actual temporary regression of the disease at a period when extension rather than regression is to be expected has been demonstrated in some cases. Pain is relieved, and the patient's well-being is increased. Maintenance can be satisfactorily achieved with cortisone, and elaborate laboratory control is not needed. The effect of the procedure on life expectancy cannot be determined at this time, because all the reports made so far have been preliminary in nature and nearly all the patients subjected to adrenalectomy have been in the terminal stage of the disease. The only indications justifying the procedure at present are clinical evidence of advanced active metastatic cancer, loss of response to both estrogen therapy and orchiectomy, and incapacitating pain or debility. The benefit afforded by the removal of androgenic elements in hopelessly advanced cases, however, suggests that early adrenalectomy may prove valuable in the treatment of early prostatic cancer. Dramatic relief of pain was secured by this procedure in two patients with advanced metastatic disease, one of whom was discharged on the 14th postoperative day with the expectation that he would soon be able to return to work. The other, who was partially paraplegic, was greatly improved and remained free from pain for the first three months. Pain then gradually recurred but was relieved by cordotomy at the D-2 level.

Bilateral Adrenalectomy in Patients with Advanced Neoplasms.—The authors report the results of removal of the adrenals and of castration in nine patients with advanced neoplastic disease who had been previously treated by surgery, irradiation, and hormone therapy. Transabdominal bilateral adrenalectomy through a long, curved transverse upper abdominal incision was performed in three patients with melanoma in whom orchiectomy was also performed at the same time. The course of the disease was not altered, and the patients died six, three, and two months after the intervention. The same approach was used in three patients with carcinoma of the breast whose ovaries were removed through the same incision. Pain was relieved in these patients who are still living, although the survival periods of six, five, and one months are too short to be significant. Pain was relieved in only one of three patients with carcinoma of the prostate. The initial treatment in these patients consisted of transurethral prostatectomy, orchiectomy, and estrogen therapy. Two have died seven and three months after adrenalectomy was performed through separate extraperitoneal flank incisions in one stage. The third is still alive six weeks after the adrenal glands were removed in two stages using the flank approach. The future course of patients with advanced neoplastic disease who are benefited by bilateral adrenalectomy is uncertain, since the regression of the tumor, whenever attained, is not permanent. The intervention is only an aggressive form of palliation for these patients. Hypotensive crises in the immediate postoperative hours may be treated with pressor agents such as arterenol. Generally it is possible to reduce the cortisone dosage to a maintenance level of 50 mg. daily within the first week. Neither diabetes nor hypertension is a contraindication to adrenalectomy if the renal function is not impaired. The intervention is contraindicated in patients with pronounced impairment of the renal function.

Tumors of Posterior Fossa with Supratentorial Symptomatoloy. R. Van den Bergh.—p. 472.

Familial Incidence and Predisposing Factors in Postvaccination Encephalitis.—Observations by others have shown (1) the existence of a familial predisposition to neurological or psychic sequelae of exanthemas; (2) the possibility that a new infection may reactivate disturbances seen in the course of a preceding exanthema; and (3) the necessity of taking old craniocerebral traumas sustained in earliest infancy into consideration when interpreting the nervous frailty of certain patients, even though they show no signs of deficit. Similar findings have been reported in patients with postvaccination encephalitic symptoms of neural impairment. The family antecedents and electroencephalographic tracings of the healthy brothers and sisters of patients with postvaccination encephalitis were therefore studied in an effort to discover subclinical signs of cerebral impairment capable of causing future disturbance. The first family consisted of the father, aged 35, healthy; the mother, 32, delicate, slightly nervous, with a tendency toward anemia; and three sons, 13, 10, and 9 years old. The eldest son had encephalitis following smallpox vaccination at the age of 9; marked sensitivity to hyperpnea was the only residual electroencephalographic disturbance. The second son was studied during an attack of encephalitis. The first tracing, made 14 days after vaccination and 10 days after the first signs of encephalitis, showed pronounced slowing and numerous delta waves with clear aggravation during hyperpnea. The second tracing, made 10 days later, was still disturbed, but the third, made one month after the onset of encephalitis, was normal for a child of the patient's age and remained stable during hyperpnea. The third son had never been vaccinated and had normal tracings. The second family was composed of healthy parents, a sister, and four brothers, aged from 20 to 30 years. The oldest brother and the sister were not examined. Two of the other brothers had no neurological complications in the course of vaccination, but presented electroencephalographic abnormalities that could be considered signs of clinically silent changes in the nervous system. The third had meningoencephalitis after revaccination at the age of 22. Electroencephalographic examination showed changes similar to those found in his brothers, but very much more pronounced. These findings indicate the existence both of a familial predisposition to cerebral reactions and of predisposing factors, such as psychic and somatic trauma or toxic infection. Conjunction of the predisposition and the predisposing factors would produce sensitization of the central or peripheral nervous system resulting in a "neuroallergic" reaction. Electroencephalography is apparently valuable as a method of detecting subclinical anomalies favoring the appearance of postvaccination encephalitic complications in predisposed families.

Vagal Body and Its Tumor.—The patient, a 36-year-old woman, complained of a swelling high up in the right side of her neck which had first appeared 11 years previously. A soft rubbery swelling was observed in the right lateral wall of the pharynx, and this had pushed the wall of the oropharynx almost to the midline of the palate. On the outer surface of the neck a similar swelling, continuous with that in the pharynx, presented between the angle of the mandible and the mastoid process. The tumor was deep to the sternocleidomastoid muscle and showed no fluctuation. Exploration of the tumor was carried out through an incision parallel to the anterior border of the sternocleidomastoid muscle after which the muscle was divided transversely at its upper insertion. The tumor was covered by a network of blood vessels and this extreme vascularity made its exposure difficult. A cavity the size of a large hen's egg, through which the carotid artery ran a sinuous course, remained after the removal of the tumor. The patient's postoperative course was uneventful except for a right recurrent laryngeal nerve palsy and paralysis of the right half of the tongue. At the time of writing this report the patient remained well. On pathological examination of the removed tumor it was classified as a small mass of hyperplastic tissue closely resembling the carotid body in its structure, and situated in or near the ganglion nodosum of the vagus nerve. The normal vagal body is a somewhat diffuse lobulated mass of vascular cellular tissue; its structure and innervation has been shown to be similar to that of the carotid body. The vagal body is grouped with the carotid body and similar masses of tissue as chemoreceptor bodies, which are not considered to have any relation to the chromaffin system. The general close histological resemblance of the tumor to the normal vagal body in conjunction with the encapsulation of the tumor, paucity of mitoses, and apparent benign clinical course were sufficient to make the author cautious of accepting any claims of neoplasia. As far as can be ascertained the present case is the fourth of a vagal body tumor to be reported in the literature.

*Mucoepidermoid Carcinoma of Parotid Gland: Case in Girl 8 Years Old. H. Salce, A. Aguirre, M. Salas and others.—p. 166.

Mucoepidermoid Carcinoma of Parotid Gland.—Mucoepidermoid carcinoma of the parotid gland is very rare in children. Five cases have been reported in the American literature. The case reported in a girl 8 years old is the first reported in the Mexican literature. The parotid tumor grew slowly for one year. It was painless at first and later became very painful and opened in two fistulas. Partial resection of the parotid gland was made. Histological study of the surgical specimen showed a mucoepidermoid carcinoma with formation of a large cyst and of a large number of small cysts. The patient was in satisfactory condition after the operation. However, in less than a month she complained of the appearance of a hard nodule in the sternocleidomastoid muscle. A biopsy proved that the nodule was of the same type as the tumor previously removed. Total parotidectomy with radical dissection of the tissues of the neck, in a block, was made.

The tumor included numerous small cysts. Metastases were identified in the lymph nodes of the lateral chain of the neck. Local irradiation was given in the postoperative period. Only a few months after the operation the patient had gained some weight. Sequelae from the operation and the irradiations are peripheral facial paralysis and local edema. A prognosis cannot be ventured, because of the lack of experience with tumors of this type in children.

Temperature and Pulse of Surgical Patients With and Without Postoperative Thromboembolism.—An abnormal drop in temperature and discrepancies between temperature and pulse were previously described by the authors as a characteristic sign of threatened thromboembolism. The incidence of these symptoms was reported in 288 surgical patients with postoperative thromboembolism and in 288 patients without this complication. Absolute values of measurements of temperature and pulse before the surgical intervention and during the postoperative course in these two groups of patients are reported and compared in the present paper. Results showed that high temperature and high pulse rate in patients with an uncomplicated postoperative course corresponded with the sympathetic phase that is elicited exclusively by the operative stimulus. The increase of the sympathetic tonus, therefore, induced a simultaneous increase of temperature and pulse rate. Patients with threatened thromboembolism already presented a greater lability of the pulse before the operation than those in whom there is no threat of thromboembolism. The impending surgical intervention as well as other psychic excitement during the day preceding the operation are to be considered as a stimulus which may increase the pulse rate in patients with a labile autonomous nervous system. A high increase of temperature but not of pulse rate in the sympathetic postoperative phase characterized the patients less than 60 years of age with threatened thromboembolism. Patients over 60 with threatened thromboembolism did not show a high increase of temperature in the sympathetic phase. There were no differences in the pulse rate between the patients in the sympathetic phase. A high pulse rate with very low temperature in the parasympathetic phase strongly indicated threatened thromboembolism. Temperature and pulse depend on the function of the central-autonomous nervous regulation apparatus. This apparently is disturbed in patients with threatened thromboembolism.

*Ganglioplegics in Essential Hypertension. C. Bartorelli and R. Rumolo. —p. 3.
*Ion-Exchange Resins. I. Pannacciulli.—p. 40.

Ganglioplegics in Essential Hypertension.—Hexamethonium salts were given intravenously, intramuscularly and orally to 60 patients with essential hypertension. The systolic and diastolic pressures dropped in all the patients. The hypotensive effect was correlated with the route of administration. It was the same when hexamethonium was given intramuscularly or intravenously to patients in the lying position. There was a greater pressure fall when the drug was given intravenously to patients in the standing position, but the hypotensive effect lasted longer when it was administered intramuscularly. The individual response to the drug varied, especially when it was given orally. Orthostatic collapse is the major side-effect of hypotensive therapy, and it is commonest when the parenteral route is used. It does occur also after oral administration of the drug. Side-effects are more frequent after oral administration, and they affect mainly the digestive tract. Severe constipation is the commonest. In many cases this side-effect may be prevented with laxatives or neostigmine (Prostigmin) although these may interfere with the hypotensive therapy. Experimental and clinical data indicate that the cerebral, coronary, and renal circulations are not impaired if the hexamethonium-induced hypotension is not too pronounced. Great caution should be taken before instituting this therapy in patients with arteriosclerotic or other type of vascular lesion. Caution should also be used in patients with diabetes and in pregnant women. In the former the therapy potentiates the hypoglycemic effect of insulin and in the latter the fetus may reabsorb some of the hexamethonium from the amniotic fluid, since the placenta barrier is permeable to this ganglioplegic. This therapy is contraindicated in patients with angina pectoris, cardiac infarct, and renal complications.

Ion-Exchange Resins.—The author reports on the ion-exchange resins and their importance in medicine. The anion-exchange resins have given good results in the treatment of gastric ulcer and hyperacidity of pregnancy. The cation-exchange resins have greater importance because of their capacity to restrict the absorption of sodium. They are indicated mainly in the treatment of edema if combined with a moderate sodium intake. Good results have been reported in patients with edema due to heart insufficiency, liver cirrhosis, and renal disease. They were also beneficial in pregnant women with eclampsia and potential edema. Their use has been attempted in patients with hypertension, potassium deficiency due to cortisone therapy, and hyperpotassemia. They should be administered orally in doses of 15 gm. three to four times a day near meals in conjunction with a moderately low sodium intake (2 to 5 gm. daily). The best results are obtained when they are administered in repeated courses of 5 to 10 days with a treatment-free interval of 2 to 3 days between each course. The side-effects of treatment with resins are acidosis, especially in patients with renal insufficiency, potassium deficiency, and severe constipation. Granular casts with traces of albumin have been found by some authors in the urine of persons and animals treated with resins, but since they did not find any organic alteration in the tubules they attributed them to the increased urinary acidity. Tremor and psychic effects may follow administration of resins to patients with liver disease. Sulfonamides, saline purgatives, and salt substitutes should be avoided during administration of resins, and digitalis should be used with caution.

*Treatment of Neurosyphilis with Penicillin. H. J. Dammann and E. Schmidt.—p. 1231.

Penicillin in Neurosyphilis.—In 1950, 12 million units of penicillin G sodium were given in aqueous injections of 200,000 units over a period of 10 days to 29 women and to 19 men with neurosyphilis. Of the 48 patients, 18 had cerebral and cerebrospinal syphilis respectively, 1 had cerebral gumma, 12 tabes, 5 progressive paralysis, 1 syphilitic meningitis, 1 syphilitic atrophy of the optic nerve, and 9 had latent syphilis with positive cerebrospinal fluid. Except for a few, these patients did not receive any further treatment up to 1952 when follow-up examinations were performed on 20 of the 48 patients. Pleocytosis and increase of the total protein values had been reduced within six months after the termination of the treatment in most of the patients, and these values had remained low without further treatment. As compared to results of the first examination six months after the termination of the penicillin treatment, the number of cells was reduced in one additional patient, and reduced total protein values were observed in two additional patients. The stained test that had revealed improvement in 17 patients six months after the termination of the treatment did not show any additional improvement. The reaction of the cerebrospinal fluid to the Wassermann test had within half a year after the treatment become negative in two cases, and within two years in two additional cases. The reaction of the blood to the Wassermann test showed a similar behavior. All the patients stated that they felt better subjectively and that their work capacity was improved. Objective neurological and psychiatric findings were not changed. The authors state that penicillin proved adequate for the treatment of neurosyphilis and metasyphilis. Improvement in the cerebrospinal fluid occurs within the first six months. Normalization of the cerebrospinal fluid within the next one to two years was observed in only a few cases. Comparison of the results obtained with the penicillin therapy in the 48 patients with those obtained in 17 patients who had received combined neoarsphenamine, bismuth, and malaria therapy indicated that the results were of practically equal value. The advantages of the penicillin treatment consist of the simpler application and the much rarer occurrence of complications. The much shorter stay in the hospital required for the penicillin treatment as compared to the combined chemotherapy and malaria therapy is an additional factor in favor of the penicillin treatment. The authors believe that preference should be given to penicillin therapy. Combined treatment with penicillin and bismuth is at present the method of choice.

Relation Between Thyroid and Menstrual Cycle in Baboon.—The thyroids of 10 adult female baboons were completely removed at various stages during the menstrual cycle. The baboons were over 7 years of age, having passed through puberty some four years previously. The cycles of each animal were followed by daily inspection and measurement of the sex skin for at least one year and in some instances for three to four years before thyroidectomy. The rhythmical changes in the perineum, the duration of the component phases of turgescence and deturgescence, as well as the total length of the cycle of the 10 baboons, fell within the normal range. After thyroidectomy the parathyroid glands were carefully dissected out of the thyroid, and were reembedded in the deep fascia of the neck. The possibility that tiny fragments of thyroid tissue remained after surgical ablation could not be discounted. Ten normal female adult baboons over 7 years of age constituted the control series. Disturbances in the menstrual rhythm occurred in the 10 female baboons whose thyroids were removed, which indicates that the thyroid gland is closely connected with the regulation of the normal menstrual cycle. Day-to-day examination of the perineal reactions provided evidence, first, that the removal of the thyroid gland profoundly modified ovarian activity and, secondly, that ovarian function, as reflected by the perineum, ranged from inhibition, associated with suppression of perineal cycles, to interference with ovulation and persistence of estrogen stimulation with irregular perineal cycles. Although the menstrual cycle was disturbed in all baboons whose thyroids were removed, the exact disturbance varied from one baboon to another. From a reconstruction of the events encountered in the endometrium, it was evident that after thyroidectomy a rhythm did occur, albeit strikingly different from that seen in the normal baboon. Attention was drawn to the difficulty of assessing the endocrine function of the ovaries from the structure of the endometrium. In attempts to unravel the complex and variable reactions of the uterus, perineum and ovaries in baboons following thyroidectomy, consideration was given to the role of the pituitary gland. Suggestive evidence was available to the effect that derangement of ovarian function observed in such baboons was the consequence of a widespread metabolic disturbance involving not only a modified gonadotrophic activity of the pituitary but also a modified responsiveness of the ovaries to the pituitary hormones.

Spread of Staphylococcus in a Maternity Department.—What determines an outbreak of severe sepsis such as pemphigus neonatorum in a maternity department or infants nursery where Micrococcus pyogenes var. aureus (Staphylococcus aureus) is prevalent? To answer this and other still unsolved problems, an investigation was undertaken, which aimed to ascertain, first, whether strains of M. pyogenes var. of aureus spread from nose to nose in a community in the absence of severe sepsis as readily as when sepsis is present? Secondly, whether all strains of M. pyogenes var. aureus isolated from hospital communities are of potentially equal virulence and, if not, can this be demonstrated in the laboratory as claimed by Knott and Blaikley? The department studied had had no severe cases of staphylococcic sepsis for a considerable time, although cases of mild conjunctivitis were common. Over a period of four months swabs were taken from the anterior nares of mothers on admission and on discharge and of babies on discharge. Similar swabs were taken from the nursing and the medical and domestic staff on three occasions during the investigation. A number of swabs were also taken from mothers during the course of their stay and from various samples of dust and bedding. There seemed to be evidence that certain strains of potentially pathogenic staphylococci were spreading round the department. Over half the nurses were nasal carriers of penicillin-resistant M. pyogenes var. aureus and the predominating phage-type was 52A. Many mothers in the short period of 10 days apparently picked up penicillin-resistant strains of M. pyogenes var. aureus of phage-type 52A. The noses of 75% of the babies became colonized with M. pyogenes var. aureus; in nearly 90% of carriers the strain isolated was penicillin-resistant and in a third of the cases it was phage-type 52A. Study of the type of strains isolated from babies, mothers, and nurses indicates that the babies picked up staphylococci more readily from the nurses than from their mothers. No definite answer can be given to the question of why there was no severe sepsis, despite the fact that it must be assumed that potentially virulent strains of penicillin-resistant M. pyogenes var. aureus were spreading. From the bacteriological point of view it is bad to herd babies together in a ward, into which a nurse goes to attend to them one after another. In the department here studied there was not even running water in the baby wards, so that in order to wash between handling each baby the nurse had to leave the room. It was not her practice to change her gown between attending to each infant. A rearrangement of maternity departments with separate units for each mother and baby seems desirable. Recent observations have shown that both the total nasal carriage rate of M. pyogenes var. aureus and the incidence of resistant strains are much lower among babies born in the comparative privacy of their own homes than among babies born in hospitals.

Fluorine and Dental Caries.—Amies and Pincus discuss fluoridation of water supplies as a measure for prevention of caries. In discussing certain biochemical aspects of fluorine in water and certain articles of diet, Amies and Pincus direct attention to the influence of the drinking of tea on the intake of fluorine in Australia and New Zealand. As an example, they cite Dunedin, New Zealand, where the municipal water supply contains 0.05 ppm of fluorine. From ordinary infusions of tea (without milk) made with this water, it was calculated that tea could contribute from 0.45 to 0.93 mg. of fluorine per day when the tea ration allowance was 8.1 gm. per day. This would indicate that the average person can obtain approximately 1 mg. of fluorine per day from tea. This amount has been suggested as the optimal intake of fluorine for preventive effects. A person who is a heavy consumer of tea without milk, therefore, cannot afford to take in more fluorine than that already provided by tea, without exceeding the suggested optimum. Current investigations in the United States have demonstrated a temporary partial control of dental caries in young children by the artificial fluoridation of municipal water supplies. Nothing more can be claimed at present. Adequate dental treatment and oral hygiene continue to be essential. Investigations in England in areas in which fluorides occur naturally in water revealed that the caries incidence in 12-year-old children who consumed such drinking water was less than that in control groups; but a survey of 15-year-old children indicated an equal incidence of caries in both groups. This merely demonstrated a three year lag. It is also pointed out that fluorine is a powerful inhibitor of enzymes and a bactericidal agent for some bacteria. The actual chemical form in which sodium fluoride exists after addition to municipal water supplies has not been determined; its physiological ability to be assimilated may be of a different order than that of fluorine occurring naturally in water. The cumulative storage of fluorine in the skeleton and the serious effects of toxic fluorosis have been noted in recent years. The difficulty of statistically assessing the incidence of caries in young children is discussed.

Regional Lymphadenitis and "Cat Scratch Disease."—During the last two years nine adults and six children with a peculiar regional nonbacterial suppurative lymphadenitis were studied in Queensland. The clinical behavior of these 15 patients and the microscopic detail of the affected glands presented a striking similarity to the lymphadenitis occurring in patients with "cat scratch disease." Of 10 patients from whom a reasonably complete history was obtained, 6 gave a history of contact with cats, and of these, 3 stated that they had been scratched or bitten not long before the onset of the lymphadenitis. All three patients on whom an intradermal test was carried out with the "cat scratch" antigen supplied from London gave a positive reaction. Thus the authors believe that the condition observed in Queensland is identical with the disease described as "cat scratch disease" in America, England, and France. The disease is thought to be caused by a virus of which the cats may act purely as passive carriers. There was no noticeable response of the patients either to sulfonamides or to penicillin, but recovery occurred without sequelae. Although the disease will follow a benign course in most of the cases, there is evidence to suggest that the condition may not necessarily be always benign or localized in character.

Genital Carcinoma in Elderly Women: 1,169 Cases in Women Over 60. P. Paracchi and L. Luciani.—p. 355.

Megaloblastic Anemia of Pregnancy.—The problem of megalobastic anemia developing during the last months of pregnancy has not been solved. Since the fetus accumulates iron during its intrauterine life and thus alters the systemic iron balance of the mother, there may be a tendency, even if only a potential one, toward a deficiency of iron in the pregnant woman. The constitution of the person must play a great part in this complication. Women who are predisposed to blood diseases have a lesser defensive power against the fetus-placenta toxins which are liberated during pregnancy. Some authors believe that diet alone, even if rich in iron, cannot prevent the onset of anemia in these persons. Lack of vitamins and the action of the estrogens, which are increased during pregnancy, may also be responsible. The changed endocrine balance affects the bone tissue, and these modifications have repercussions on the anatomic and functional balance of the bone marrow. The hemopoietic organs become unable to counterbalance the erythrolysis and erythrocatheresis that are increased during pregnancy, and megaloblastic anemia develops. The author reports on two young women in whom this complication appeared suddenly during the eighth month of pregnancy. Labor began prematurely in both, and blood transfusions were performed. Liver extracts combined with vitamin B_{12} had poor or no effect, but there was a good response to massive doses of folic acid and iron and the blood picture of both patients was much improved. Although blood transfusions and other therapies have improved the prognosis of megaloblastic anemia of pregnancy, its pathogenesis still remains obscure.

Findings and Considerations on Some Cases of Tumors in Children Hospitalized During Last 15 Years in the University of Naples Pediatric Clinic. L. Auricchio and G. Murano.—p. 451.

Cancer in Families of Children with Leukemia.—The author investigated the relationship between malignant tumors and leukemia. He analyzed the genealogical tree of 75 children with leukemia treated at the Gaslini pediatric clinic from 1942 to 1952 and of 75 children who did not have the disease. He found one case of cancer in the family of nine children with leukemia and two cases in the family of one child. Cancer was never present in the parents of these children. It was found in seven of the paternal and four of the maternal grandparents. The incidence of neoplasms was higher in the families of the 75 control children, with one case of cancer in the family of 16 of them, two cases in the family of one, and three cases in the family of one. Cancer was found in the father of one child and in 13 of the paternal and 7 of the maternal grandparents of these children.

Blood Pressure in Patients with Steatorrhea.—De Langen investigated the blood pressure in patients with sprue, since Salvesen, in determining the blood pressure of 84 patients with idiopathic or symptomatic steatorrhea, had observed that nearly all had subnormal blood pressure and that the mean pressure in all was considerably below that of a group of healthy persons of the same ages. De Langen's case material differed from that of Salvesen, since, among 136 patients with steatorrhea studied by him, there were 102 with tropical sprue. Salvesen apparently had not had a single patient with tropical sprue. Despite this difference, however, de Langen was able to confirm that his patients, like those of Salvesen, had low or very low blood pressure. Salvesen had suggested that hypotension might be due to the fact that these patients have a disturbance in the absorption of a substance, probably a lipid, which is essential for the maintenance of an adequate blood pressure. De Langen, however, suggests that the hypotension is not the result of the steatorrhea but rather that the sprue syndrome develops as the result of a circulatory deficiency of the intestinal wall.

Follow-Up of Patients with Exophthalmic Goiter Following Subtotal Thyroidectomy.—Seven postoperative deaths occurred among 227 patients treated with subtotal thyroidectomy after preoperative diiodotyrosine treatment. Of the 33 who sent information by letter on the follow-up from 1 to 10 years after the operation, only three reported inability to carry on their daily work. Dollerup and his associates found the results good in 94% of the 150 patients examined in the hospital, with 28.7% fully recovered, 46% with full ability to work and normal metabolism and slight residual symptoms, and 19.3% better able to work than before the operation; in 6% the capacity for work was reduced and there were marked subjective and objective symptoms. Shorter duration of the disease before operative treatment seemed to affect the outcome favorably. Of the total 51 with cardiac symptoms on the follow-up, 41 had normal capacity for work; cardiac symptoms were noted in only 27 of the 39 who had cardiac symptoms before operation. True relapse occurred in 4%.

BOOK REVIEWS

Medical Schools in the United States in Mid-Century. By John E. Deitrick, M.D., and Robert C. Berson, M.D. Cloth. $4.50. Pp. 380, with 14 illustrations. McGraw-Hill Book Co., Inc., 330 W. 42nd St., New York 18; 95 Farringdon St., London, E.C.4, 1953.

This volume constitutes the report of the Survey of Medical Education, which was organized in 1947, sponsored, and financed by the American Medical Association, the Association of American Medical Colleges, and the W. K. Kellogg Foundation. It is a factual self-analysis and evaluation of medical education in the United States at mid-twentieth century, based on a survey of 41 carefully selected representative institutions. Conclusions are based on facts and opinions obtained from deans, faculties, and medical students and represents an authoritative current evaluation of medical education, its leadership, function, and finances in the United States. The increasingly complex nature and ever-widening scope of responsibilities and activities of today's medical school are well portrayed and analyzed. Modern medical school functions are indicated to be education, research, and service, so interwoven in most instances that the costs of medical education have not been clearly differentiated from the research and service aspects. The dangers to medical education itself of overemphasis of either research or service activities are clearly implied and the necessity of maintaining a proper balance of these activities emphasized.

Medical school finances are examined in detail, and an analysis is made of the funds involved and how they are spent. Medical schools in operation are evaluated from the standpoint of administration, medical school-hospital relations, departments, faculty, and student admisison problems. The undergraduate curriculum has been subjected to careful scrutiny, and the responsibilities of medical schools in advanced education and training are discussed at length. The authors have presented "a summing up" in their final chapter that will undoubtedly provoke much discussion among medical educators and others interested in this field. This chapter focuses attention on the following questions: What is medical education? What is a medical school, and what are its responsibilities? Should research be the major goal of a medical school and receive the greatest financal support? What is the goal of the medical school in providing medical care?

It is difficult to separate some phases of education and training, and what different medical schools may do in this regard will vary greatly. Locale, finances, service functions, and many other factors naturally emanating as part of different educational programs present variables that continue to keep medical schools from becoming stereotyped. The size of the school and the complexity of organization may be significant problems but need not transcend quality if all factors are properly adjusted. Tradition and authority will continue to be hurdles to progressive curriculum adjustments until broader perspectives are attained by those interested in medical education and departmental barriers are minimized. Certain trends leading young physicians into a philosophy of dependence rather than independence in leadership are pointed out.

There are useful appendixes evaluating student opinions on college preparation and their medical school impressions, analyzing current medical school administrative problems, outlining the distribution of graduates from four-year medical schools and the distribution of libraries, postgraduate education, and finances. This new survey of medical education, like the Flexner Report that appeared in 1910, will be of value to the medical schools and all those interested in medical education, by stimulating further analysis and advances in this field. Today's problems are vastly different from those in 1910 but, nevertheless, present intriguing challenges. In 1910 the Flexner Report brought about a badly needed revolution in medical education that resulted in placing it on an increasingly high plane over the years. The current report tends to focus the complex problems of education, research, and service in medical education today and makes recommendations that should be seriously considered by medical schools and universities in their efforts to solve them. The volume should be read and thoughtfully analyzed by all who are interested in medical education and its ramifications.

Medical Education Today: Its Aims, Problems and Trends. By Joseph C. Hinsey, Director, New York Hospital-Cornell Medical Center, New York City, et al. Edited by Dean F. Smiley, Secretary, Association of American Medical Colleges, Chicago. Paper. $1.50. Pp. 123, with 7 illustrations. The Journal of Medical Education, Association of American Medical Colleges, Rm. 1001, 185 N. Wabash Ave., Chicago 1, 1953.

This is a compilation of papers that appeared in recent issues of the *Journal of Medical Education* dealing with important problems confronting medical schools and educators in this dynamic period of readjustment. The seven articles were written by leaders in the field of medical education and constitute an interesting and timely presentation of the problems confronting medical education with an evaluation of potential solutions. The first paper is the eighth revision of the objectives of undergraduate education as they are conceived by the Association of American Medical Colleges today. It clearly portrays the major aims of undergraduate medical education and endeavors to indicate its limitations. Other papers present the problems of staffing medical colleges in four-year medical schools, problems revolving around the selection of medical students, a presentation of the financial status of medical education, an analysis of the distribution and characteristics of medical college graduates during the period from 1915 to 1940, and a final article presenting the challenges confronting medical education at this time. This volume deserves serious review by all medical educators, college presidents, and members of the profession concerned with the problems of medical education.

More Clinical Sonnets. By Merrill Moore. Cloth. $3. Pp. 72, with illustrations by Edward Gorey. Twayne Publishers, 34 East 23rd Street, New York 10, 1953.

Dr. Moore's latest collection of sonnets can be reviewed by repeating comments that have been made about the author's previous sonnets. The sonnets have been described on various occasions as "magnificent"; as expressing "humor and poignancy" and making for "diverting reading"; as "providing acute insight expressed with wit"; as being "pithy, caustic, comic, tender, penetrating, sad, grim, witty, serious"; and as inviting the reader to "start reading and stop if you can." It can only be added, "For the reader who may have an inhibition, a quick cure resides in this edition."

Introduction to Physiological and Pathological Chemistry. By L. Earle Arnow, Ph.G., Ph.D., M.D., Vice-President and Director of Research, Sharp & Dohme Division of Merck & Co., Inc., West Point, Pennsylvania. Revised with assistance of Marie C. D'Andrea, R.N., B.S., Educational Director, School of Nursing, St. Vincent's Hospital, Indianapolis. Fourth edition. Cloth. $3.75. Pp. 508, with 108 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1953.

So many textbooks of chemistry for nurses have appeared in the last decade that none would reach its fourth edition if it were not exceptionally good. Like the other three editions, this text is simply written, copiously illustrated, and pointed to the interests of student nurses. The major changes from previous editions are deletion of directions for laboratory experiments (to be published in a separate manual) and instructions on the removal of stains from clothing, and addition of separate chapters on nuclear reactions and atomic energy, on agents used in chemical warfare, and on the chemistry of blood. Throughout this book the material has been brought

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any official bodies unless specifically so stated.

up-to-date; for example, cortisone, corticotropin, and cyanocobalamin (vitamin B_{12}) are discussed. The printing is of good quality and the binding is sturdy, but the highly glazed paper, which may have been necessary for the illustrations, is hard on the eyes of readers. All instructors in this field will wish to examine this textbook.

Who Shall Survive? Foundations of Sociometry, Group Psychotherapy and Sociodrama. By J. L. Moreno, M.D. Cloth. $10. Pp. 763, with illustrations. Beacon House, Inc., P. O. Box 311, Beacon, N. Y., 1953.

This book is apparently not a first edition, although no mention of earlier editions is made on the title page. In it the author says someone once asked him, "Why is the first edition of 'Who Shall Survive?' so clumsily written?" to which he replied: "In order to make it clear for all posterity that the book could not have been written but by myself alone." In another place he says some one said to him: "You seem to think that 'Who Shall Survive?' is a book of books, a new bible." Moreno admits that it is a new bible, that it has more ideas packed in one book than a whole generation of books, and adds that actually he has written two bibles. The book is a formidable volume and contains a wealth of information on the subjects of sociometry, psychodrama, and group psychotherapy, intermingled with ideas on philosophy, religion, sociology, and countless other fields of thought. In addition, there is a vast amount of tabulated and statistical data as well as a lengthy bibliography. For those interested in such material and in the broad fields to which they apply or for those who are anxious to learn about some of the feelings and philosophical ideas of the author, the book will be of interest. It is written by the man who has generally been given credit for originating group therapy and psychodrama. So far as priority in the field of sociometry is concerned, Moreno offers as the frontispiece to the book a fragment of the "First Sociometric Plan" in the form of a fragment from the original draft of his letter written in 1916 urging the Austro-Hungarian monarchy to apply sociometry to the community of displaced persons in Mittendorf. Elsewhere in the book he says, "I tried to do through sociometry what 'religion without science' has failed to accomplish in the past and what 'science without religion' has failed to accomplish in Soviet Russia." The future will have to determine whether he has succeeded in achieving this ambitious aim.

Lehrbuch der topographischen Anatomie. Von Anton Hafferl, o. Professor der Anatomie und Vorstand des anatomischen Instituts der Universität Graz. Cloth. 60 marks. Pp. 921, with 664 illustrations. Springer-Verlag, Reichpietschufer 20, (1) Berlin W. 35 (West-Berlin); Neuenheimer Landstrasse 24, Heidelberg; Göttingen, 1953.

This fine book on topographical anatomy is the result of much planning and an extensive survey of the available texts and literature. Although numerous standard works deal with this subject, the author has used a fresh approach, and has succeeded in presenting the common anomalies as well as the so-called normal anatomy. The color plates add appreciably to the clarity with which the structural relationships are depicted. The use of red to denote suture lines is particularly helpful.

The following faults detract but little from the value of this work. The discussion of the relationship of the facial nerve to the parotid gland was especially weak. Greater emphasis should have been placed on the possibilities of the nerve passing between the superficial and deep parotid lobes. Figure 208 on page 250 depicts a most unusual looking thyroid gland. No isthmus is shown, and one lobe seems to merge directly into the other. In this same illustration a pyramidal lobe is shown arising from the upper aspect of the right thyroid lobe. Such an origin is rarely, if ever, noted. Although the embryologic development of the pancreas is admirably treated, there should have been more stress on the fact that the common duct travels through the head of the pancreas. Furthermore, this fact was not brought out in figure 356 on page 454. The cystic duct appears out of proportion in figure 366 on page 474. The sections on the extremities were very well done. The book is printed in large type, and an attempt has been made to shorten the sentences. The latter feature should prove a boon to those whose reading knowledge of German is not fluent. An extensive bibliography is appended.

Tests and Standards for New and Nonofficial Remedies: Containing Tests and Standards for Nonofficial Drugs and Dosage Forms Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1953. Issued by The Chemical Laboratory, American Medical Association. Cloth. $4. Pp. 327, with illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; Aldine House, 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1953.

This small volume is a companion to "New and Nonofficial Remedies" from which tests and standards were omitted for the first time this year. To make the volume independent of N.N.R., structural formulas have been included in the individual monographs and trade names of Council-accepted brands have been added. Aside from these changes the work is what used to be section B of the annual editions of N.N.R. Substances covered in this volume are nonofficial dosage forms of official products and drugs not in the "United States Pharmacopeia" or the "National Formulary." Many of the nonofficial drugs are too new to be in the official compendiums, which are published at five-year intervals. Thus, the volume is useful to pharmacists, pharmaceutical manufacturers, purchasing agents, and students of pharmaceutical chemistry. The printing and binding are good.

Multiple Myeloma. By I. Snapper, M.D., Director of Medical Education, Cook County Hospital, Chicago, Louis B. Turner, M.D., Research Assistant in Medicine, Mount Sinai Hospital, New York, and Howard L. Moscovitz, M.D., Resident, Second Medical Service, Mount Sinai Hospital, New York. Cloth. $6.50. Pp. 168, with 43 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1953.

This excellent monograph is based, for the most part, on the authors' extensive study of 97 cases of multiple myeloma, 41 of which were studied post mortem. The discussion of various aspects of the disease encompasses the experience of the authors and relates it to previous findings in the literature, which is fairly completely reviewed. The text is well written and is liberally supplemented by illustrations that are generally very good. The lithography and format are also commendable. The bibliography and index enhance the book's value, even though the bibliography does not pretend to be complete. The main function of the book is to serve as a definitive treatise on the subject to date. Hematologists will certainly want the book for their libraries, and others will do well to browse through it, because multiple myeloma, by virtue of the multiplicity of its manifestations, may be encountered in almost any specialty. Perhaps the greatest value of the book is to call attention to the fact that multiple myeloma is not at all a rare disease, as evidenced by the ability of the authors to collect 97 cases in one institution in seven years.

United States Government Organization Manual 1953-54. Federal Register Division, National Archives and Records Service, General Services Administration. Revised as of July 1, 1953. Paper. $1. Pp. 734. Superintendent of Documents, Govern. Print. Off., Washington 25, 1953.

Because the activities of the federal government are so closely interwoven in the lives of all citizens, it is only natural that curiosity should arise concerning the structure of this government. The manual of the United States Government Organization is revised each year and is the sort of volume that provides ready reference for anyone interested in the make-up of the government, the activities of the departments, the personnel associated with these departments, and other such information. It should be of interest to almost all citizens but often offers particular interest to special groups, for example, members of the legal profession, physicians, and business men. This volume is well worth the dollar it costs, even if it serves no other purpose than to provide an answer to questions that arise concerning discussions of politics. The entire family will refer to this at some time during the year.

QUERIES AND MINOR NOTES

STERILIZATION BY DRY HEAT

To the Editor:—*At what temperature should the thermostat of a hot air sterilizer be set and how long should it continue for the sterilization of needles, syringes, small instruments, and rubber gloves?*

H. H. Hancock, M.D., Union, West Va.

Answer.—Clean needles, surgical instruments, and syringes can be sterilized by exposure to dry heat at 160 C (320 F) if the sterilization interval is sufficiently long. Usually, exposure for one hour, after the temperature has been attained, is sufficient. If the sterilizer is overloaded or if the heat must penetrate outer covers such as glass tubes or metal trays, the time should be extended. It is recommended that the temperature of the oven be raised gradually to 160 C to permit adequate heat penetration and to prevent excessive strains on glassware. Rubber goods will not withstand exposure to dry heat at the temperature and interval required for sterilization.

THALAMIC SYNDROME

To the Editor:—*A white woman, aged 44, was suddenly stricken four years ago with severe headache with lateral deviation of the right eye. Lumbar puncture revealed blood in the spinal fluid. Cerebral angiography revealed an aneurysm of the right internal carotid artery in the anterior portion of the circle of Willis. Ligation of the carotid vessel on this side was followed within 24 hours by complete left-sided hemiplegia and unconsciousness. Anticoagulant therapy brought excellent improvement. The patient is ambulatory and doing well, except for slight weakness of left arm and left leg with insignificant sensory changes on the left side. One year ago, she began to complain bitterly of a "waxy" sensation in the mouth. Qualified staff members at a recognized dental school had no explanation but suggested that this was a psychosomatic manifestation. This waxy sensation has been unrelenting. She has no interference with taste sensation, but states that periodically there is a hot feeling in her mouth. She complains of a tingling sensation, which is constant over the lower maxilliary and mandibular divisions of the trigeminal nerve bilaterally. It cannot be relieved by mouth washes or any type of food. Can you suggest any therapeutic approach?*

M.D., Alabama.

Answer.—The persistent symptoms and "insignificant sensory changes on the left side" point to a limited lesion within the ventral posteromedial nucleus of the thalamus on the right. Crossed and uncrossed secondary trigeminal pathways have been traced to this nucleus. This would account for the bilateral symptoms. The lesion is in all probability a gliotic area that arose as the result of anoxemia occurring at the time of rupture of the aneurysm or during the critical period after carotid artery ligation. The lesion of necessity is small, since such a limited portion of the body is involved. No specific treatment can be recommended for this condition, which is known as the "thalamic syndrome." Stellate ganglion blocks with procaine could be tried on the chance that the symptoms that were delayed in onset are caused by a vasospastic phenomenon associated with irritation at the junction of normal neural tissue and the area of glial scarring. If the symptoms increase to the point of becoming unbearable for the patient and drug addiction threatens, major neurosurgical intervention must be contemplated. In this event prefrontal lobotomy could be considered or one of the stereotoxic procedures recently devised by Wycis for interruption of ascending pain pathways in the mesencephalon.

SMALLPOX VACCINATION

To the Editor:—*Is it true that giving smallpox inoculations without the prior preparation of the skin with an antiseptic agent is a serious break in sound medical principles? It is felt that the intradermal prickings of an inoculation could be compared to shaving, the pressure of a belt or other clothing, the simple rubbing of the skin unconsciously, or the "sandpapering" of acne scars, where there is no thought of artificially induced infection.*

M.D., Virginia.

Answer.—When the skin is cleansed with acetone or ether in preparation for a smallpox vaccination, the area should be dry before the vaccine is applied. To facilitate speed in vaccinating large groups, nurses or medical assistants usually do the preliminary work. With such an arrangement, the physician is concerned only with the actual vaccination and there is no loss of time. If there are failures to secure successful vaccinations in susceptible persons, the potency of the vaccine should be investigated. Vaccine that has not been stored at a low temperature may have become useless. It would be a serious error to ignore the customary technique for cleansing the skin before the vaccine is applied. There is always the possibility of an infection with staphylococci and streptococci present on the surface of the skin. The inoculation of smallpox vaccine cannot be compared to shaving. Many infections have resulted from the other examples mentioned when an unclean skin was abraded, and the cut of a razor—especially on the upper lip—has led to infections that resulted in death.

ASTHMA AND SILICOSIS

To the Editor:—*Would asthma that occurs for the first time in a 52-year-old granite worker be caused or aggravated by silicosis, second stage? Roentgenograms of the chest four years ago showed no abnormalities and three years ago showed scattered mottled shadows.*

Pierre J. Guilfoile, M.D., Delano, Minn.

Answer.—Asthma occurring for the first time in a 52-year-old person can be aggravated by silicosis. The type of dyspnea caused primarily by silicosis is due to damage of the lung parenchyma and to emphysema. In some persons with silicosis, bronchospasm is induced secondarily. It should also be remembered that a 52-year-old man may have allergic infections or cardiac asthma for the first time. If the patient in question has true asthmatic episodes (relieved by epinephrine or aminophylline), a search for other causative factors should be made by a series of observations such as examination of the sputum for eosinophils and neutrophils, skin tests, and examination for hypertensive, coronary, or syphilitic heart disease.

WORK WITH VIBRATING TOOLS

To the Editor:—*May I have some information on the occupational hazard attendant to the use of a jackhammer over a period of years. I am specifically interested in knowing whether or not any type of nerve damage normally follows the continued use of one of these air compressor hammers.*

M.D., Illinois.

Answer.—A variety of physiological disturbances are attributable to the action of vibrating pneumatic and electric tools. Part of the differences in manifestations are attributable to the speed and amplitude of the vibration. Another difference is related to low temperatures attending some pneumatic tool work. As a rule, the severer conditions result from use of high frequency, low amplitude tools. The major disturbances chiefly involve the fingers and are, or are similar to, Raynaud's phenomenon. For some major tools, of which the jackhammer is one, the most frequent damage involves the soft tissues, appearing as synovitis or tendonitis. In addition, arthritis at any point along the upper extremity may result. Also areas

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

of bone decalcification may arise in the wrist area. Long nerve neuritis is not a common feature but repeatedly has been described, the ulnar nerve being mentioned oftenest. Apart from the tool itself, other factors contribute, such as the posture while at work. Some mining or quarrying operations may require a prone position, leading to much pressure on the outstretched arms. The hardness of the material being drilled is significant.

ANGINA-LIKE PAINS

TO THE EDITOR:—*A married woman, aged 26, has had angina-like pains for two years. She had one abortion at four and one-half months of pregnancy, followed by infection of the uterus and adnexa, three years ago. The cause of the abortion is unknown. She is Rh negative. She has one living child, aged 5. Two years ago, the patient had peptic-ulcer-like pains, which were partially relieved by the use of methantheline (Banthine) and Prantal (N,N dimethyl-4-piperidylidene-1,1-diphenyl-methane methyl sulfate). Results of upper gastrointestinal tract studies did not indicate an ulcer; one film showed a J-shaped stomach. For the past six months the pains have been precordial; they are severe, sharp pains that radiate to the upper left arm, stopping at the elbow. The chest pain is not affected by deep breathing or exercise but comes on at rest, while the patient is listening to music or even while she is asleep, thus waking her. Swimming and the lifting of heavy objects do not initiate the pain, and it is not related to eating or hunger. The ulcer type of pain no longer seems to be present. The patient's present distress is not relieved by the use of atropine (1/100 grain [0.6 mg.] given intramuscularly), acetylsalicylic acid, phenobarbital, Donnatal (an elixir containing hyoscyamine sulfate, atropine sulfate, hyoscine hydrobromide, and phenobarbital), antispasmodics, or antacids. The pain is severe for several minutes and then dies down, leaving a dull ache that persists for several hours. On several but not all occasions, it was relieved dramatically by the use of glyceryl trinitrate under the tongue. It commonly occurs while the patient is lying on her back. There is no pyrosis. The patient has psychiatric determinants (a broken home in her childhood), and she continues to have weird dreams. The electrocardiogram is normal. Results of roentgenographic and fluoroscopic examination of the chest are normal. The patient claims she is happily married, and she would like to become pregnant again. At an early age she was kept home from school and in bed for several months. Her athletic activity in school was restricted for a year, and she was told she had "weak lungs." She is highly intelligent and perfectionistic and is usually successful in all endeavors. The local internist is unable to find an organic lesion that could cause this pain. Have you any suggestions?*

M.D., California.

ANSWER.—Despite the seemingly obvious psychic implications of the occurrence of the symptoms on recumbency, the patient's condition probably does not have a psychic basis, nor is it likely that the chest symptoms are cardiac in origin. Although decidedly unusual, it is entirely possible that the pain is due to cholelithiasis. A Graham test should be performed. The possibility of a hiatus hernia cannot be excluded on the basis of a single examination; other types of hernia, such as those involving Morgagni's or Bochdalek's foramen, must also be considered. If none of these tests shows abnormalities, use of a therapeutic regimen that has been beneficial to patients with hiatus hernia should be attempted. This would include the eating of only small meals, avoidance of ingestion of liquids and of assuming the recumbent position for at least two hours after any meal, sleeping in as upright a position as feasible, with the use of two or more pillows or even a hospital bed, and a regime of a liberal bland diet.

HISTOLOGICAL SECTIONS

TO THE EDITOR:—*In* THE JOURNAL *of Sept. 19, 1953, page 257, the physician from the Dominican Republic asked about the time required to get a report on a biopsy specimen. Your answer stresses the making of a section and states that after the section is made the interpretation can be made the same day. The autotechnicon is an expensive complicated machine that moves the tissues through the solutions and, therefore, can process tissues during the night. If one wishes, the tissues can be moved through the same solutions by hand. When the volume of work is sufficient, this machine is of some help in getting sections. However, it is possible to process a piece of tissue and get a section in one day without an autotechnicon. The interpretation of the section and preparation and mailing of the report may take much more time. It seems to me that the physician from the Dominican Republic has no just complaint when he says that it takes as long as seven days to get a report. This can only mean that other reports require less time.*

We have three autotechnicons, and I direct one laboratory where we have no autotechnicon. In this laboratory we put formaldehyde-fixed specimens into acetone over night. The next morning they are put into a second acetone solution and then into chloroform and paraffin (two changes). Sections are made late on this day and thus are obtained 18 hours after the tissue is placed in acetone. Small pieces can be run, cut, and stained in 10 hours or even less. To this time for interpretation and report must be added. There is much more to it than getting sections.

Robert B. Wright, M.D.
University of Maryland
Baltimore.

TO THE EDITOR:—*Possibly the physician from Dominican Republic* (THE JOURNAL, *Sept. 19, 1953, page 257) will find the following method for securing histological sections advantageous. For 24 hour tissue processing a pathologist need buy no equipment more expensive than a half a dozen wide-mouthed stoppered 200 cc. bottles. He can improvise a 55 C paraffin oven with an electric lamp as a heating element; the microtome and microscope are the only expensive necessities.*

Tissues as received in 10% formaldehyde may be left until noon, and can be put into the paraffin by 5 p. m., to be ready for sectioning and staining the following morning. The tissues for examination should be cut less than 4 mm. thick and strung on colored threads or with beads for identification, so they will hang in the upper part of the solutions, supported by the stopper. Tissues obtained by curetting may be similarly strung if placed in gauze bags.

First, the specimens should be placed in alcoholic Bouin's solution, and the bottle placed in the paraffin oven for a half hour. After transfer to isopropyl alcohol (absolute), the specimen should be left for an hour in the oven and in a second alcohol solution for another hour. Then the specimen should be left in toluene in the oven for an hour (until the tissues are translucent), in a second toluene solution for a half hour, then in the paraffin overnight.

The isopropyl alcohol bottles are conveniently used with a layer of $CaSO_4$ *granules in the bottom, with an indicator. The time required to change from one solution to another as warned by a timer clock is under 1 minute (5 minutes in all). Where time and skill and training are requisite is in the orientation of tissues in the paraffin blocks, the sectioning, and the mounting on slides. Slides taken from the warm water on which they are floated and flattened can be dried of water, and the paraffin melted for rapid removal by toluene preliminary to staining, by placing the slides on a frame set over an electric lamp for a few minutes.*

PERSPECTIVE VERSUS CAPRICE IN EVALUATING TOXICITY OF CHEMICALS IN MAN

CHAIRMAN'S ADDRESS

Maurice H. Seevers, M.D., Ph.D., Ann Arbor, Mich.

Life in these United States in the mid-twentieth century is so dependent on the products of chemical technology that no field of human thought or endeavor can ignore its dominating influence. Given reasonable time, the chemist appears to be able to construct a product to meet almost any set of specifications, the limiting factor being the imagination of the designer. Developments in this field have moved forward so rapidly in the last two decades that even the pharmacologist can scarcely keep abreast of the influx of new drugs, while the toxicologist is swamped with the multitude of agricultural, industrial, and household chemicals that are flooding the market.

Many of these compounds are highly toxic by any standard. Others are potentially capable of effecting long-range biological actions about which little is presently known. The public, ignorant of these effects, deserves and expects protection against unlimited exploitation of these new substances. The question is how much protection a government can be expected to guarantee to the nation and how it shall be accomplished. It would appear to be in proper perspective to say that the least the public should expect is that the algebraic sum of beneficial and detrimental effects of any chemical substance represent a significant positive balance in favor of benefits to the person and/or the state. By the same token, it seems out of perspective to attempt to protect the public against every conceivable contingency that may occur. The quantity of technical information concerning the biological actions of old and new chemicals, even in that circumscribed area of principal interest to the physician, the effects of chemicals on man, is now so great as to pose a most difficult problem in medical education, since it is to be expected that the medical student, the general practitioner, and even the medical specialist can assimilate only a very small fraction of this mass of material.

American physicians are indeed fortunate in being able to inform their patients that drugs purchased on prescription or for self-medication are almost certain to be of proper identity, purity, quality, and quantity. This situation is virtually guaranteed by the wise provisions of the Food, Drug, and Cosmetic Act of 1938, especially the new drug section, which requires approval in advance of distribution. In the main, fair perspective has been maintained in administering the act as it relates to drugs, and the medical profession has retained the initiative in this area, probably because it is better informed about the tools it uses daily. Drugs, however, represent only a relatively small fraction of the total problem of toxicity of chemicals for man. It is also the easiest fraction with which to deal, since a greater risk is permitted and toxicity is usually easier to determine. In the fields of food additives, pesticide residues, industrial exposure, and many other situations involving borderline decisions between toxicity and nontoxicity, the problems are exceedingly difficult. In these areas, the medical profession has lost the initiative, even in many situations in which its members are the only persons with competence to make decisions critical to the public welfare.

This is not surprising and may not even be seriously detrimental to the public welfare, since decisions based on this technical information affect every facet of human activity so profoundly that they represent legitimate concern of sociologists, economists, legalists, moralists, politicians, and internationalists, as well as physicians and biologists. It is almost axiomatic that areas of activity such as these, in which opinion must often substitute for lack of factual data, may also become the province of the crackpot, the self-styled scientist, and the well-meaning but misinformed reformer. Any of these persons may exert a powerful influence on the general public by posing as a champion of the individual safety and protector of the public welfare.

It would be surprising indeed if proper perspective were to be retained by all participants in a situation involving such a large number of points of view and so many selfish interests. Who should logically bear the responsibility for maintaining proper perspective in a situation that involves such a maze of conflicting forces?

From the Department of Pharmacology, University of Michigan.

Read before the Section on Experimental Medicine and Therapeutics at the 102nd Annual Meeting of the American Medical Association, New York, June 3, 1953.

Obviously the principal responsibility for retaining perspective is in the hands of those who are authorized to administer the law and the regulations enacted under the law.

My purpose is to call attention to certain situations involving nondrug chemicals, food additives, pesticides, and other commonly used products. These facts should be of interest, since their implications represent a cause for professional as well as civic concern. As a pharmacologist, whose business it is to keep informed on matters related to toxicity, I am in a position to recognize and to view with alarm the gradually growing body of practical propagandistic pseudoscience that is being permitted to increase by those who are legally and morally responsible for retaining perspective, in order to fulfill what they believe, undoubtedly in all honesty, to be their obligation to the American public.

EXISTING LEGISLATION AND PHILOSOPHY

For approximately 50 years, the food division of the Food and Drug Administration has adhered to a basic administrative policy that no chemical shall be added to foods. This philosophy was first established, even prior to the enactment of the 1907 Food and Drug Act, by H. W. Wiley, who was then chief of the bureau of chemistry, U. S. Department of Agriculture, the predecessor of the present Food and Drug Administration. There have, of course, been many decisions that are contrary to this policy, since it is difficult to consistently find scientific support for a negative position. It is not my intention to discuss the merits of this policy but to declare what I believe to be the results in loss of perspective from adherence to an administrative policy that is not based on sound scientific principle. Lest there be any doubt that such a policy is still in existence, I quote from testimony offered by Dr. Dunbar, the recently retired commissioner of the Food and Drug Administration, before the House select committee to investigate the use of chemicals in food products, the Delaney committee: "I feel that no chemical or no new chemical that is subject to any question as to safety should be employed until its possible injurious effect, both on acute and over a long-time chronic basis, has been shown to be nonexistent. In other words, any chemical that is proposed for use ought to be approved in advance of distribution in the food product to be utterly and completely without the possibility of human injury." Strict adherence to this statement would be to deny man the use of every chemical substance in view of the unquestioned fact that no method ever has been, or ever can be, devised that will permit an exact advance prediction of human hazard. In simple terms, no competent pharmacologist, toxicologist, or clinician will guarantee that there is no risk present in making available a new chemical for widespread distribution.

Although I believe that any philosophy based essentially on prohibition is impossible of scientific defense, my concern does not stem primarily from this fact. I am much concerned, however, as a scientist, about the methods used in the name of science to support an indefensible policy. These methods are essentially based on a studied attempt to confuse and mislead the public. My remarks are not intended to be an exercise in semantics, but I wish to make my point by relating what has happened to the terms, toxicity and poisonous. These terms have become so misused and so abused by pseudoscientists, politicians, and others that they now connote almost any type of action, or reaction, whether biological, sociologic, or economic, that is reported to be inimical to the public interest. The shifting of these terms from a scientific to a lay connotation places the pharmacologist and the toxicologist, as well as the clinician, in a dilemma. They are asked and expected to do the impossible. The principal task of the pharmacologist and the toxicologist is to supply sufficient basic information concerning the biological action and potential toxicity of a chemical substance on animals to warrant its preliminary clinical study in man as a calculated risk. What is the purpose of these studies if their application to man is denied? The a priori determination of calculated risk is an exceedingly complicated problem. In many instances it must involve the considered judgment of a large number of fully competent specialists in a variety of fields, including nonbiological areas. This is especially true when prolonged and extensive exposure of a whole population is involved.

As a result of the fact that so many persons may ultimately become involved and that so many decisions may be necessary to determine the calculated risk with accuracy, the easiest position for those in fields of great responsibility to assume is one that amounts virtually to complete prohibition based solely on absolute toxicity. This can be easily accomplished by the establishment of standards that are impossible to attain regardless of conditions of use, capricious and discriminatory decisions, and the like. Such a view is easy to assume since it is most amenable to regulation, requires the least energy to defend and to administer, and requires no effort whatsoever to muster the support of the extremists, the misinformed, and the opportunists, to mention but a few. Strangely enough, the public appears to demand a share in deciding what shall be a calculated risk, although this seems contrary to the statements of representatives of this philosophy. A few examples will suffice. The per capita use of cigarettes increases each year in spite of the warnings about such deleterious effects as cancer. The per capita consumption of alcohol has never diminished appreciably, although its misuse represents one of the most important sociologic and medical problems. Did the rebellion against the Volstead Act represent a perversity of an ignorant population or did it indicate that, even though a majority of the consumers of alcohol knew its potential toxicity and its personal as well as a social hazard, they were still willing to calculate these risks to be warranted when balanced against personal and social benefits?

There is a tendency to believe, or to lead the public to believe, that the new chemical agents are fundamentally different from those old chemicals with which we have long been in contact. The inference is made that some new principles are needed for handling the problems of toxicity that arise in this advanced chemical age. These new chemicals, however, do not differ in any respect, except possibly in potency, from those with which we are more familiar. Nearly every known chemical substance can produce a toxic action on man if the exposure is adequate. In fact, selective toxicity is the basic principle that governs the activity of the large segment of the chemical industry that deals with the actions of chemicals on biological systems. This principle is basic in the search for a cure for cancer, tuberculosis, or any other disease, as well as in the search for a new insecticide, soil fumigant, or food preservative.

It cannot be denied that sensible laws and regulations are necessary to protect the public against itself and against those unscrupulous persons who would prey on the ignorance or cupidity of individual members of the population. It would appear to be neither dignified nor necessary to use shabby tactics to effect this protection. Yet short-sighted policy, incompetence, bureaucracy, and politics have resulted in such an admixture of fiction with science that it is no longer possible to distinguish truth from propaganda, and vice versa. Numerous technical devices that prohibit rather than aid the determination of the factual state as it relates to toxicity have become established over a period of time; for example, the use of the terms adulteration and standards of identity as virtual synonyms for toxicity has become common administrative practice. Other examples include the use of arbitrary margins of safety without much regard for the conditions of use, transference of toxicity data from its application in one use to an instance in which the data apply to another use, without consideration of the hazard or calculated risk in the latter usage, the denial of established facts based on experience with large groups of human beings if these facts deviate from findings in other animal species, and the use of incompetent witnesses or pseudoscientists to bolster up administrative decisions and influence legislation.

One of the best recent examples of this type of action relates to the decision that bans softeners in bread. These cannot be considered to represent a biological hazard under present conditions of use. That softeners may not offer sufficient material benefit to society to warrant their use is not the point. The real point is how the problem was solved administratively in order to muster support for the decision to discontinue the use of softeners. This was done by declaring the manufacturers guilty of "deceptive" practices in the name of toxicity because these substances had not been shown to have been nontoxic throughout the whole lifetime of man. If this is perspective, then the scientist had better go out of business.

OUTLOOK FOR FUTURE LEGISLATION

Prolonged adherence to a philosophy of action that places the burden of proof on the administrator, as is the case with foods under the present law, is no easy task especially when capricious decisions are under constant attack. As is inevitably the case when technical progress exceeds human capacity to deal adequately with a problem, solution is sought in further legislation. Theoretically, this should represent a gain to the state since, in principle, laws are enacted to enable society to retain or regain perspective rather than the converse.

Be that as it may, new legislation is now being considered that will set up a so-called new chemical section of the federal act that will deal with foods and food products, and will be analogous to that now in use for new drugs. The principal provision of this proposed legislation would be to require proof of the nontoxicity of chemicals in advance of their use. I do not intend to discuss the merits of this new legislation, except to say that I believe that it could be as beneficial as the present new drug section providing it was formulated, enacted, and administered with perspective based on scientific fact. I believe that physicians, who obviously have a vital concern with this problem, should be apprised of the total situation as it now exists, since such new legislation if administered by the existing philosophy would assure a permanently distorted approach to the problem.

In order to effect such legislation, an "impartial" committee of the House of Representatives to investigate the use of chemicals in food products was impaneled to hold hearings on the problem. In the midst of these hearings, the chairman, James P. Delaney of New York, published an article in the July, 1951, issue of the *American Magazine*. This lurid article, a masterpiece of innuendo and fantasy, based principally on conjecture, was designed for the one purpose of frightening the housewife into demanding further legislation. Mr. Delaney stated: "The Food and Drug Administration has listed 704 chemicals which are being used in our regular food supply, of which only 428 are known to be safe. In other words, 276 chemicals are unknown and untested quantities, and some of them may be slowly poisoning us!

"This potentially lethal situation is due to a curious loophole in our present laws, a tragic legal joker that permits us to become a nation of 150,000,000 guinea pigs guilelessly testing out chemicals that should have been tested adequately before they reached our kitchen shelves.

"Doctors testifying before the House committee have stated that there may be some connection between these new chemicals and the increase of such diseases as cancer, polio, and the mysterious virus X."

It is interesting to note that laymen also testified before the committee, on medical subjects. "Louis Bromfield, novelist and gentleman farmer, testified that virus X, the mysterious, influenza-like epidemic disease, may be nothing more than manifestations of DDT poisoning; and the increased incidence of heart disease, cancer, and leukemia may result from cumulative poisoning by pesticide residues."[1] Evidently, medical evidence from a layman was just as convincing to the House committee as that from the doctors.

Examination of the testimony that was collected with the active backing and support of the regulatory agency involved and was offered before the Delaney committee reveals it to be largely of the caliber just mentioned. For example, nitrogen trichloride (Agene) has been used in the United States for over 25 years to age and bleach flour. A few years ago, it was discovered that this compound produces convulsions in dogs. Although the American people, for 25 years, have been using bread made of flour bleached with this agent, there is no evidence that it has had any deleterious effect on them; yet several self-styled experts, writing in the press and testifying in the Delaney hearing, conjectured or inferred that epilepsy, alcoholism, and a variety of compulsive, convulsive, and excitatory disorders may have resulted from the use of this material for the last 25 years. Millers and bakers "voluntarily" agreed to abandon its use. I would not object to this action even if legal compulsion had actually been required to enforce it. In this particular instance, the justification for use is so negligible that the calculated risk must be equally negligible. I oppose vigorously, however, the capricious use of these data even to infer toxicity for man. This is more reprehensible since it was designed primarily, if not exclusively, to influence legislation.

---

[1] Coming: Tougher Food Law, Chemical Week, vol. 69, No. 2 (July 14) 1951, pp. 11-12.

If a negative experiment on man involving a 25 year trial in a whole population (possibly 2.5 billion man-years) is ignored as proof of nontoxicity, what conceivable type of evidence could a pharmacologist or a clinician present in advance of distribution in a food product to be utterly and completely without the possibility of human injury?

In defense of the competent and experienced scientists associated with these regulatory agencies, let me say that they are often forced by their position to render decisions in the face of innumerable pressures, even though they often lack the definitive information necessary to an adequate decision. This is likely to become worse rather than better. For this reason, some measures should be taken that would permit them to share responsibilities in areas in which they lack competence. Let me cite a few examples of current or future headaches. Chemicals for systemic use that are effective in population control are now available. Can a few administrators with small technical staffs deal adequately with this problem? The problem of carcinogenicity of chemicals stands as an ever present shadow over those responsible for making decisions. There is no possibility of devising experiments on animals that will conclusively guarantee in advance freedom from such an action in man. Are we to deny ourselves the trial use in man of all chemicals because of a possible carcinogenic effect? Chemicals that will alter genetic characteristics in plants, modify their growth, and produce numerous modifications of their biological characteristics have long been known. It is only a matter of further study to find such chemicals that will produce similar effects in man. Probably they will be discovered by accident. In all likelihood, they will not be ascertained in advance. The imagination of the reader may furnish even tougher assignments for the future. Undoubtedly, if most of us were confronted with such problems we would fumble and possibly lose perspective. I hope, however, not to such a degree as to advocate 10 year administration of chemicals to the monkey before admissibility for use in man as was advocated by a well-meaning witness in testimony before the Delaney committee. As one who knows from 25 years' experience how difficult it is to maintain monkey colonies for even a few years, I doubt that the witness has much competence in this area.

CONSIDERATION OF BASIC PRINCIPLES

Is there a better solution to the problem of properly evaluating toxicity of chemicals for man without resorting to the unscientific methods already alluded to? Without offering a categorical answer to this question, it appears timely at least to reconsider what I believe to be certain irrefutable principles upon which evaluation of human toxicity must be based. 1. Every chemical substance has a nontoxic and a toxic dose for man; that is, no chemicals must be poisons, and all chemicals can be poisons. 2. The use of every chemical substance by man, whether it be as a food, drug, cosmetic, insecticide, or for any purpose, is a potential hazard. There are only few exceptions. The risk may be very small or very great, depending on the nature of the chemical, the conditions of use, the degree and duration of exposure, and the condition of the person. 3. The toxicity of chemicals for man can be ultimately determined only by experiments on man. Studies on many species of infrahuman forms can give reasonable assurance that the chemical may be tried in man with a minimal risk, but no set of conditions involving animals alone can prove nontoxicity or toxicity for man. The determination of certain types of potential toxic effects such as genetic changes or carcinogenicity may require several generations or a lifetime of large human populations. It cannot be determined conclusively on any other animal species. On the basis of numerous examples of specific toxic action limited to a single animal species, it is safe to conclude that some day a chemical will appear that is specifically toxic for man alone. 4. The use of every chemical substance in man involves a calculated risk. The degree of risk is calculated by balancing the toxicity of the chemical under conditions of use (its hazards) against its benefits to man, whether these benefits are direct or indirect. Minimal risk is encountered when the dose or extent of exposure is calculated to be tolerated by the weakest member of the population. This would take into account every person who may be specifically sensitive to the chemical. For chemicals designed for internal use or capable of being absorbed into the body, it is impossible to predict with certainty in advance a quantity of the material, or establish a regimen of exposure, or to calculate a margin of safety, which will at the same time assure complete biological effectiveness and absolute nontoxicity in any human population. In other words, the maximal tolerated dose for the weakest member of a population may be ineffective in the most resistant, whereas an effective dose for the latter may be toxic to the former. The common practice of arbitrarily assuming a so-called margin of safety for man, calculated on the basis of data on animals, usually a quantity or concentration tenfold to one-hundred-fold greater than that shown to produce minimal injury in animals, is at best no more than a means of permitting preliminary experiments in man. At its worst, when used as a substitute for human experience, it arbitrarily eliminates from consideration substances that may be of great practical value. In any event, scientific considerations would demand that such calculations be discarded entirely in the face of human data. 5. The greater the benefit of a chemical substance to man, the greater the justification for the increase in risk in its use. For example, an invariably fatal disease justifies the use of severely toxic compounds. As much as 10% expansion of a national food supply by the use of a food preservative or a pesticide would appear to justify a greater degree of risk than that ordinarily permitted in foods in view of the world responsibilities this nation is being called on to assume. In countries where critical food shortages exist, the individual risk could be very materially increased when it is balanced against national malnutrition and death from starvation.

On the basis of these considerations, we are now, and we will always be, confronted with two distinct and difficult problems, even after the pharmacologist has completed his studies on animals. First, the actual determination of toxicity in man. This requires now, as it will always require, pilot scale use of chemicals in man under controlled conditions in order to ascertain whether full scale use on the whole population may be justified. Such a procedure is inevitably associated with a certain calculated risk. Neither legislation nor regulation will alter this fact. The only obvious solution to this problem appears to be "limited use" acceptance until sufficient data in man are collected to arrive at a conclusion. This type of approval obviously could be justified only in the light of careful evaluation of justification for use. The only alternative, from a scientific and medical point of view, is for the public, satisfied with the *status quo*, to declare a moratorium on further technological advance in the chemical field and individually and collectively to refuse to play the role of Mr. Delaney's "guileless guinea pigs."

The second problem is the determination of justification for use in the light of all the biological and social forces existent in the population. In the latter area, no satisfactory agency or mechanism exists with the composite know-how and vision to deal satisfactorily with this problem, nor does it seem desirable to create such a permanent agency, because each new problem requires a different background in skills and experience for an equitable decision. The real defect in our thinking at the national level has been that, whereas we have created the mechanism for accurately determining toxicity in animals and we know how to determine toxicity in man with a minimal risk, the most difficult facet of this problem, the determination of justification for use, has not been kept in proper focus. It does not seem likely that perspective can be easily gained when any person may assume competence and get a respected hearing without regard to his training, experience, or judgment in these difficult areas, in our lawmaking tribunals.

It would appear that a satisfactory solution to both problems might be gained by the use of *ad hoc* committees implemented by qualified persons of wide experience and judgment in the principal areas under consideration. Such a technique, while not relieving the regulatory agencies of responsibilities assigned under the law, would have the obvious advantage of at least assuring the public of valid technical as well as moral justification for decisions that might otherwise be made without perspective. Such a commendable plan, operating within the framework of the National Research Council, was utilized most effectively in bringing perspective to a difficult problem dealing with toxicity of one of the antibiotics. Expansion of this technique into other branches of knowledge as they relate to this whole problem of toxicity would appear to be a most worth-while experiment. Finally, the public should be informed as to the facts. In the final analysis, it is the citizen who would like to assess the calculated risk for himself.

CHOLECYSTOGRAPHY IN INFANTS

Ruth C. Harris, M.D.
and
John Caffey, M.D., New York

Roentgen visualization of the gallbladders of infants has been consistently unsatisfactory and has been of little value in diagnosis of lesions of the biliary tract. Satisfactory cholecystograms have been commonly obtained in patients older than three years when the adult dose of either tetraiodophenolphthalein or iodoalphionic acid (Priodax) has been used.[1] As a rule, films have been taken about 14 hours after the oral administration of contrast material.

In 1945 Hrdlicka, Watkins, and Robb [2] reported that they had obtained satisfactory gallbladder shadows in two infants 9 and 10 months of age and in three of four infants 12 to 18 months of age. Iodoalphionic acid was used in doses two or three times the usual adult requirement per kilogram of body weight. In infants from one to seven months, no satisfactory gallbladder shadows appeared. Films were made 12 to 18 hours after the oral administration of the contrast agent diluted with orange juice.

In 1951, Catel [3] stated that visualization of the infantile gallbladder is maximal at 6 to 8 hours after the intravenous injection of 0.05 gm. per kilogram of body weight of tetraiodophenolphthalein. His patients were maintained on a diet of tea, boiled rice, and saccharin for the day preceding the test. The age of the youngest patient in whom a satisfactory gallbladder shadow developed is not stated by Catel.

The appearance of the gallbladder shadow after the oral administration of radiopaque material depends on adequate absorption, active secretion of material by the hepatic cells into the bile ducts, and concentration within the gallbladder. With these facts to guide us, we are reporting work in progress in the study of gallbladder function in infants.

GROUP AND TECHNIQUE

We have studied 20 infants and children younger than three years after oral ingestion of iodoalphionic acid or iodopanoic acid (Telepaque) under slightly varying con-

ditions and 3 infants after administration of sodium acetrizoate (Urokon) intravenously. Since we did not know the exact time of maximal concentration of these agents in young patients, hourly films were made after the administration of contrast material, usually from the 3rd to the 10th hour, with occasional later films. All but three patients received 0.15 gm. of drug per kilogram of body weight. This dose was chosen because it had not produced toxic symptoms in Hrdlicka's patients.

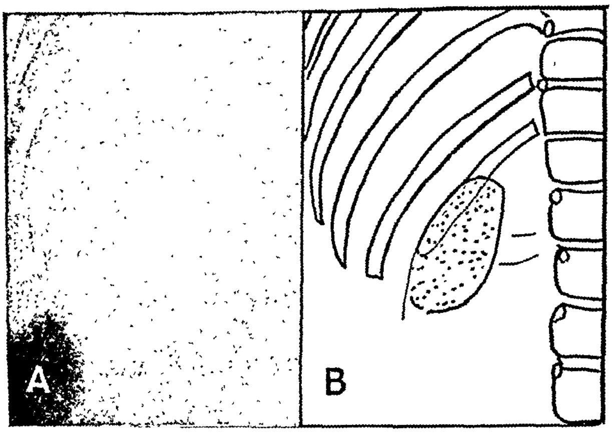

Fig. 1 (case 2).—*A*, cholecystogram showing gallbladder from frontal projection 6½ hr. after third 12 hr. dose of iodopanoic acid (Telepaque); *B*, schematic representation of the same.

The following technique was used. Nothing was given orally after midnight. At 6 a. m. either powdered iodoalphionic acid or iodopanoic acid was mixed with two or three teaspoonfuls of orange juice and then swallowed by the infant. No food or fluid was given during the next eight hours when films were made hourly, first in frontal projection only and later also in left anterior oblique position. Then, if the study was to be continued, more orange juice or Karo water was given. When films were taken as late as 24 hours, infants under six months were fed only Karo water and skimmed milk, while older patients were fed a fat-poor food. No untoward effects were noted and neither vomiting nor diarrhea occurred during the few days after the examinations.

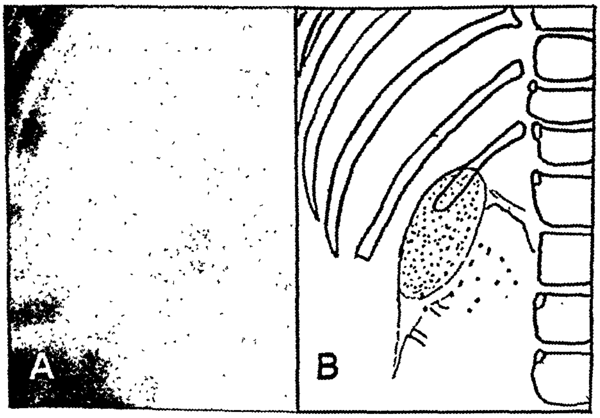

Fig. 2 (case 2).—*A*, the same as fig. 1*A* 7½ hr. after third 12 hr. dose of iodopanoic acid (Telepaque), *B*, schematic representation of the same.

At first iodoalphionic acid was used alone. In the first four patients, however, there were two failures of visualization of the gallbladder, and, in the other two, the gallbladder shadows were too faint for satisfactory interpretation. The large amounts of opaque material visible in the intestinal tract suggested that poor absorption of the contrast agent was a major cause of the failure of visualization of the gallbladder. Since iodoalphionic acid is soluble in an alkaline medium only, it is presumed that in these children the hydrogen ion concentration of the small intestine was not sufficiently low to give adequate absorption. This was supported in part by our finding that, of 24 infants under three months of age who had normal trypsin levels of duodenal juice, only 13 had a duodenal pH as high as 7. In the other 11, the duodenal pH ranged from 5.0 to 6.5. For our subsequent experiments in gallbladder visualization, therefore, sodium bicarbonate was added to the combination of orange juice and iodoalphionic acid in dosage of 0.5 or 1.0 gm.

Among eight infants so examined, satisfactory visualization of the gallbladder was obtained in five ranging in age from 3 to 17 months. In one of these five, a distinct shadow was present only in the 9 hour film. In the remaining three, no gallbladder shadow appeared in one 44-day-old infant or in a 3-month-old infant, and a faint shadow was seen in a 42-day-old infant.

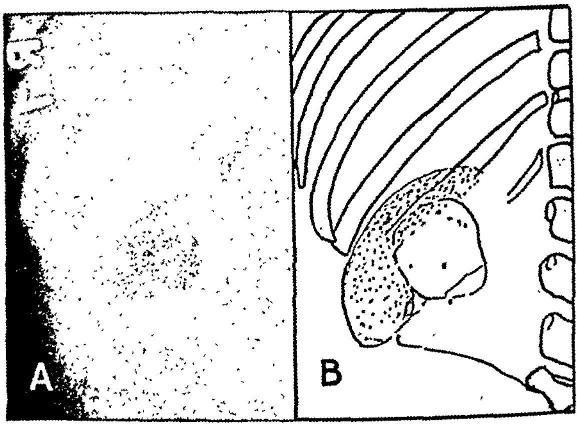

Fig. 3 (case 2).—*A*, the same as fig. 1*A* 8½ hrs. after third 12 hr. dose of iodopanoic acid (Telepaque); *B*, schematic representation of the same. Note that gallbladder shadow is almost obscured by gas in the hepatic flexure of colon.

Early in 1952 iodopanoic acid became available, and the remainder of the examinations were made with this material without added sodium bicarbonate. Results were excellent in patients older than 11 months. There were, however, failures in two infants aged 38 days and three months. Iodopanoic acid had been given in doses of 0.15 gm. per kilogram of body weight. Accordingly, 0.45 gm. of iodopanoic acid per kilogram of body weight was given in three divided doses at 12 hour intervals to the 3-month-old infant (case 2), and the first films were taken 2½ hours after the last dose. A distinct gallbladder shadow was seen at 6½, 7½, and 8½ hours (fig. 1, 2, and 3), and no shadow was seen 14 or 27 hours after the third dose. No clinical evidence of toxicity was observed after this large dose of iodopanoic acid. Since this infant had hydrocephalus and the dosage was based on body weight, she received a relatively larger dose of iodopanoic acid than would a normal infant of the same weight (table 1). We used diiodofluorescein in a 0.04 gm. per kilogram dose to study this same patient by the intravenous technique. The gallbladder shadow was seen only in the five hour film, at which time the blood level was 2% of the calculated initial blood level of dye. This timing indicated that no improvement in technique could be obtained by using this dye intravenously in an effort to eliminate intestinal absorption.

A 2-month-old infant was given 0.2 gm. of iodopanoic acid per kilogram of body weight divided into two 12 hour doses; his films made 6 to 10 hours after the second dose did not show a gallbladder shadow. In a 14-month-old infant (case 3) with acute pancreatitis, no gallbladder shadow was seen 4 to 12 hours after 0.15 gm. iodopanoic acid per kilogram were given. Two more doses were given at 12 hour intervals. Four hours after the third dose, the gallbladder shadow was intense and remained so for 8 hours (fig. 4). A third infant (case 1), aged one month, also given three 12 hour doses of iodopanoic acid, had a good shadow from 4 to 10 hours after the third dose but had no shadow after a single dose (fig. 5 and table 1). Iodopanoic acid in dosage of 0.1 gm. per kilogram of body weight was given to six children between 3 and 12 years of age with good visualization of the gallbladder shadow on single films from 10 to 18 hours after ingestion of the material.

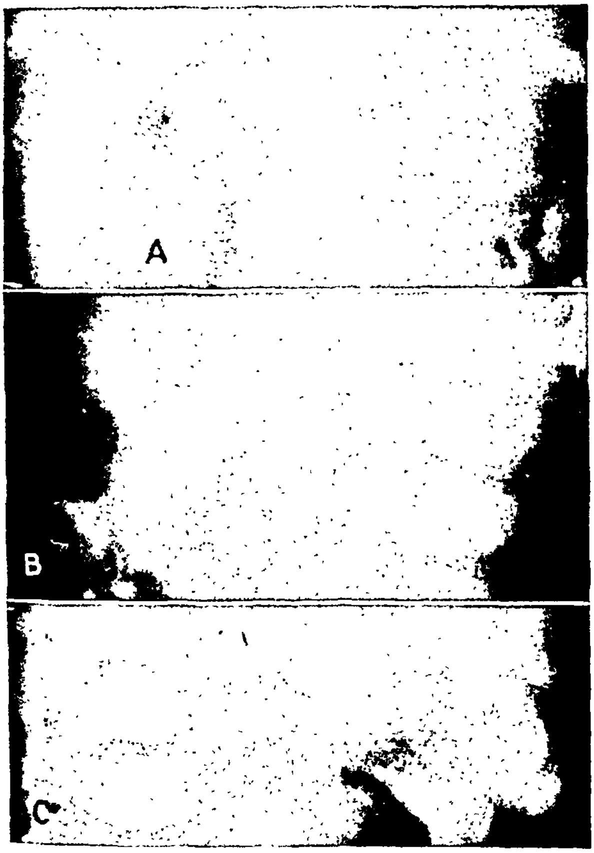

Fig. 4 (case 3).—Cholecystograms showing gallbladder 10 hr. after the third 12 hr. dose of iodopanoic acid (Telepaque) in *A*, posteroanterior, *B*, right lateral, and *C*, left anterior oblique positions.

The figures in table 2 present the time of roentgen examination in each patient and the density of the gallbladder shadow at each hour after the contrast material was given. The comparative density of the shadows was determined by a combination of visual appraisal and the aid of a densitometer. The gallbladder shadow was greatest between the fourth and ninth hour after the ingestion of the contrast agent in infants with normal biliary tracts. When the gallbladder shadow was seen in only one of a series of films, it was seen in films made at the fourth, fifth, or ninth hour.

The delayed excretion of contrast material by a diseased liver is illustrated in case 11. This infant had neonatal hepatitis with persistent jaundice until seven months of age. The sulfobromophthalein (Bromsulphalein) test at 11 months showed only 2% retention of dye in 30 minutes, but after the administration of iodopanoic acid filling of the gallbladder was delayed so that a good gallbladder shadow was not obtained until the 11th hour, and the most distinct shadow appeared at the 27th hour. After 52 hours the shadow had disappeared.

The gallbladder shadow failed to appear in six infants younger than 5 months and in a 10-month-old baby with brain damage who died one week later. Absence of the gallbladder shadow may have been factitious; it may have been obscured by the heavier shadows of iodopanoic acid in the hepatic flexure of the colon, by an accumulation of gas in the right upper quadrant (fig. 1, 2, and 3), or by improper positioning of the patient. The gallbladder shadow is not seen in the frontal projection of films of a 3-year-old child because of excess gas shadows but is well outlined in the left anterior oblique position. Films were made 11 hours after administration of 0.1 gm. per kilogram of iodopanoic acid and 40 minutes after a fat meal. This was an unsuccessful attempt to opacify the bile ducts during evacuation of the gallbladder following oral ingestion of fat. Shehadi[4] has reported that visualization of the bile ducts is possible in 50% of adult cases during the phase of contraction of the gallbladder when iodopanoic acid has been given.

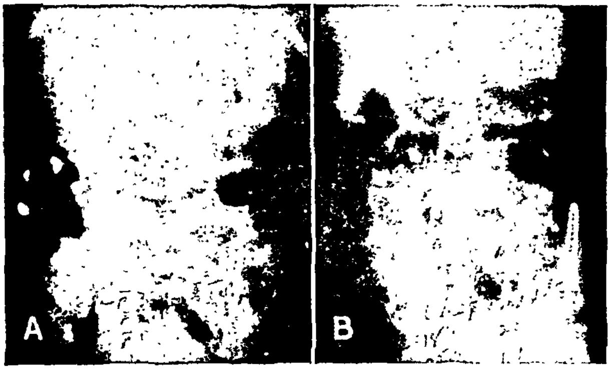

Fig. 5 (case 1).—Cholecystograms taken 6 hr. after the third dose of iodopanoic acid (Telepaque) in *A*, posteroanterior, and *B*, left anterior oblique positions.

Of interest is the finding that 5 hours after 1.4 gm. per kilogram of 70% sodium acetrizoate given intravenously to a 9-year-old boy for angiocardiography, both gallbladder shadow and outline of renal pelves and bladder were distinct. An attempt to use this technique in a 9-week-old infant, one of 3 months, and one of 5 months resulted only in good visualization of renal structure.

---

[4] Shehadi, W.: Brochure on Telepaque, New York, Winthrop-Stearns, Inc., 1951, p. 8.

Intravenous administration of sodium decholin has been advised [5] to speed the flow of bile and thereby to permit earlier visualization of the gallbladder shadow. No information is available regarding its oral use for such a purpose. Administration of 0.125 gm. of dehydrocholic acid by mouth to one patient who also received iodopanoic acid resulted in no evidence of gallbladder shadow within the next four hours. This single trial was not an adequate test and more studies must be undertaken.

Other causes of failure of visualization may be related to the degree of gastric acidity or intestinal alkalinity. This latter problem we have considered and believe that the addition of sodium bicarbonate to iodoalphionic acid may have improved the intensity of the gallbladder shadow. However, since we had no control studies wit iodoalphionic acid alone in the same patients, this mus be investigated further. It is said that patients with duo denal ulcers have poor gallbladder shadows despit adequate intestinal absorption of dye.[6] Since we have no examined the gastric secretion of any of these patient the part acidity plays is difficult to assess. It is know that gastric acidity is normal at birth and thereafter de clines during the first month of life [7] but then graduall increases throughout the rest of the first year.[8] Whethe these variations from a low of 10 cc. of 0.1 N hyd chloric acid to the higher levels of 35 to 50 cc. have a effect on the flow of bile and secondarily on the conce trating power of the gallbladder has not been tested.

We noted fluctuation in intensity of the shadows (ta 2) during the period of observation. This polycyc phenomenon has been described by Graham in adu and is caused by the emptying of the gallbladder a subsequent reabsorption of the agent into the portal sy tem. Since intestinal mobility in young infants is grea than in older persons, perhaps failure of visualization caused by too rapid excretion of material and inadequa reabsorption into the portal vein. If this is so, "loading" with larger doses at 12 hour intervals may solve the difficulty of inadequate concentration of contrast material.

SUMMARY

Twenty-seven cholecystographic examinations of 25 patients under 3 years of age were performed with 15 successful visualizations of the gallbladder. Among 12 infants under 6 months of age given iodoalphionic acid (Priodax) or iodopanoic acid (Telepaque), visualization was successful in 6. Iodoalphionic and iodopanoic acid were given orally in dosage of 0.15 gm. per kilogram of body weight. In four patients, double and triple doses were given without toxic effects. Sodium bicarbonate given with iodoalphionic acid did not clearly aid in absorption of the contrast material. Sodium acetrizoate (Urokon), 70%, given intravenously in dosage of 0.7 gm. per kilogram, did not make the gallbladders of three infants opaque.

The gallbladder shadow was most distinct in the majority of cases between 4 and 9 hours after administration of the contrast material. In three patients the gallbladder shadow was seen in only one film out of several exposed. This demonstrates the necessity for taking serial films, in general, earlier in young children than in adults. Some of the technical difficulties in cholecystography in infants are discussed.

3975 Broadway (Dr. Harris).

PRACTICAL POINTS IN MANAGEMENT OF CORD BLADDER

Gershom J. Thompson, M.D., Rochester, Minn.

In 1936, at a meeting of the Section on Urology,[1] I reported the performance of transurethral resection on the vesical neck of a paraplegic man; the operation resulted in great improvement in urinary function. This patient had sustained a fracture of the spinal column and was incontinent of urine but months later finally had regained vesical control. Shortly thereafter he could urinate only with great effort exerted by the abdominal muscles. The transurethral operation made it possible for him to void freely and empty his bladder completely but still control urination.

In a previous publication, Braasch and I[2] outlined some of the theoretical and practical aspects in patients who had atonic bladders, including a number of patients who had neurogenic vesical dysfunction. In an article with Jacobson,[3] I examined the problem further and described 10 patients; 6 of them were adults varying in age from 24 to 52 years in whom the neurogenic dysfunction resulted from myelodysplasia. Transurethral operations had been done in all 10 in an effort to improve vesical function. It was demonstrated that patients who had varying degrees of urinary retention, some complete, were able to empty the bladder after operation. Even though sphincteric resistance was reduced by the procedure, the majority of these patients had no incontinence.

Nesbit and Gordon,[4] in 1941, reported "too great an imbalance between the obstruction by the spastic internal sphincter and the forces available for evacuation" often was present in patients who had sustained traumatic lesions of the spinal cord and cauda equina. They also stated: "transurethral resection of the internal sphincter may so relieve the vesical outlet obstruction as to allow satisfactory periodic evacuation." Emmett and Bisquertt[5] have further described the experience at the Mayo Clinic with this problem. Because of early experiences with transurethral resection, I employed this operation during World War II to relieve symptoms in a group of sailors and marines who had received injuries to the spinal cord. This work was summarized in 1947.[6]

The literature is replete with articles concerning injury to the spinal cord. Prather[7] and Bors,[8] among many others, have written about this subject, and it might be presumed that nothing more need be said to clarify any aspect of the problem. Some of the material presented, however, has been somewhat complicated; therefore, it appears worth while to attempt simplification of the subject as much as possible and to present an outline of the management of a patient afflicted with neurogenic vesical dysfunction for the physician who encounters only occasionally such a patient. Some practical suggestions will be made concerning what should be done during the several phases of recovery.

GENERAL ASPECTS

The care of the urinary tract, including the bladder, is only a small part of the treatment required by the patient who has an injury to the spinal cord. The urologist manages the urinary aspect of the problem, while other physicians explore the damaged cord, apply body casts, institute measures to avoid decubitus ulcers, and direct other phases of early rehabilitation, especially the physical therapy necessary to smooth recovery. Covalt and associates,[9] in an excellent article, have reviewed many of the important points in nursing care during the early

phases in the patient who has injury to the spinal cord and have made a splendid plea for early laminectomy and for early physical rehabilitation.

The attention required by the urinary tract, especially the bladder, during the period of recovery can be discussed conveniently from a practical standpoint by dividing it arbitrarily into three stages, namely, early, intermediate, and late. Actually, no clear division is present, and, of course, no positive time schedule can be applied. The rapidity of recovery varies considerably for a number of reasons, among which are the severity of the lesion and the thoroughness and efficiency of nursing and medical attention.

EARLY STAGE OF RECOVERY

Immediately after onset of paralysis, a Foley type of catheter, size 16 or 18 F., should be used for vesical drainage. Plain roentgenograms are made to determine the site and extent of injury to the spinal column. Early laminectomy is almost always advisable, although in certain instances, because of coincidental lesions or lack of facilities, it cannot be done immediately. As a rule, a body cast is applied; hence, it is not feasible usually to do excretory urography during the first few weeks. The catheter should be irrigated several times daily and changed once or twice weekly to avoid plugging of its lumen by excessive deposition of calcium. The catheter should be connected with a closed system of drainage, all the tubes and bottles should be carefully sterilized, and all irrigations should be done with thorough aseptic precautions. A liberal intake of fluids and a diet containing extra protein, or use of protein supplements given intravenously, are usually necessary. In men, injection of testosterone may enhance the metabolism of protein.

An excretory urogram should be made as soon as it fits into the rest of the program. The possibility of formation of calculi in the kidneys and ureters must be borne in mind. If fever develops, it is usually caused by obstruction somewhere in the urinary tract. Relief of the obstruction might require only better attention to the catheter; if obstruction is caused by a stone in the upper part of the urinary tract, ureteral catheterization might be necessary to dislodge the stone.

Nesbit and Gordon [10] proposed that neurogenic vesical dysfunction be divided into four groups. Emmett and associates [11] listed six types in their classification. Jacobson,[12] after studying a series of 16 dogs in which he had produced cord bladders by the section of certain terminal nerves or of the spinal cord at various levels, proposed three types: (1) the atonic bladder, (2) the autonomous bladder, and (3) the automatic or reflex bladder.

In attempting to classify any dysfunction or to predict the type of functioning bladder that a patient might ultimately have, I consider that the most important thing to remember during the first stage of recovery is that it is often impossible to be sure how completely the nerve tracts have been interrupted. This is true even with the advantage of examination of the damaged spinal cord during laminectomy. Impairment of the transmission of impulses might be only temporary, as the result of spinal shock; what appears to be hopeless paralysis can disappear.

As the months go by after injury, the physician with great optimism repeatedly tests the patient to note to what level sensory and motor functions descend. The urologist unavoidably becomes interested in sensory dermatomes, as well as which nerves supply the various muscles of the abdomen and extremities. But during these early months, he will generally confine his urologi efforts to the care of the catheter and the judicious us of urinary antiseptics or antibiotics. These should b employed only during febrile periods, for they will no sterilize the urine while the catheter remains in the urethra. The constant prophylactic use of an antiseptic, eve extremely small doses, is unwise practice.

INTERMEDIATE STAGE OF RECOVERY

Depending on the severity of the initial lesion and ho well complications have been avoided, the patient migh recover considerably within three or four months. Th location of the lesion, as well as whether it has cause complete or incomplete transection of the spinal cor now becomes important.

It has long been recognized by physiologists, ana omists, and urologists that the center for micturition i located in the conus medullaris, in the terminal portio of the spinal cord just above the cauda equina at the lev of the 12th thoracic and first lumbar vertebrae. Bors stated that "neurogenic bladders resulting from lesio above the conus differ functionally from those wi lesions at or below the conus." In his experience wi 623 patients who had injuries to the spinal cord, thos who had no evidence of injury to the conus had reflex automatic bladders, in a great percentage of instance In contrast, when the injury damaged the conus or caud equina or both, a nonreflex type of bladder almost alwa resulted. The experience of most urologists who ha observed a large number of patients who have neurogen bladders coincides with that of Bors.

When rehabilitation has reached the stage of ambul tion, removal of the catheter can be considered to dete mine what type of vesical function, if any, has returne At this time it is usually best to perform a cystoscop examination to determine whether fragments of sto have formed in the bladder. If any such fragments a present, they can be crushed and removed with a forcep The patient is then allowed to go without a catheter f two or three hours. If an automatic bladder has deve oped, the patient will void during that time, provide that the intake of fluid is sufficiently liberal. An efficie automatic bladder will expel the urine forcefully; n residual urine will be found, or at most 1 or 2 fluid ounce (about 30 or 60 cc.) may be present. Catheterizatio should be done to determine the presence or absence residual urine.

In the patient whose injury is at or below the conu the so-called cauda equina lesion, the urine is not, as rule, expelled automatically. The patient usually note a sense of fulness or distention; if instructed to strain th abdominal muscles, the patient often can initiate urination. Sometimes the first efforts are a failure and it i necessary to reinsert the catheter for another week or two of drainage. When the patient can accomplish urination and can pass 8 to 10 fluidounces (approximately 240 to 300 cc.) or more in one voiding with little or no residual urine, vesical function can be regarded as efficient.

The patient who sustains injury to the cervical portion of the spinal cord and who has quadriplegia persisting for many months gains little if an automatic bladder develops. In most cases it is preferable to continue with drainage by means of an inlying catheter; however, if there are enough nurses available to manage the urinal, the male patient may prefer to use it rather than the catheter.

That the situation is not always hopeless in cases of prolonged paralysis caused by injury to the cervical portion of the spinal cord is illustrated by a patient who was treated some years ago. This man had a broken neck, and after three months he could barely move his hands. He could walk after nine months, although his gait was spastic. He did not have an automatic bladder, but he voided voluntarily with great effort. I performed a transurethral resection 27 months after the injury; since that operation, the patient has been able to void easily in large amounts and has good control.

Some urologists use the cystometer to measure the force exerted by the vesical wall or make cystometrograms to obtain a certain pattern of vesical activity before the patient is allowed to go without a catheter and make his first attempts at voiding. I have not used this refinement but instead have observed the patient carefully during the first few hours after removal of the catheter; no adverse effects have been noted from omission of cystometric study.

LATE STAGE OF RECOVERY

When six months have elapsed after injury to the spinal cord, it might be said that the late stage of recovery has been reached. As previously stated, this is an arbitrary interval and not one on which any firm convictions as to alteration of therapy can be based. Depending on the patient's general condition, the same therapeutic methods might be continued for several additional months. Those patients whose progress has been slow and in whom reasonably efficient vesical function has not developed should then be reexamined carefully. Another excretory urogram should be made, with a search for stones or evidence of severe infection. Cystoscopy should be repeated and the appearance of the vesical neck and wall carefully noted. Any calculi found in the bladder that might not have been detected by the urogram can be removed. Cystitis of important degree may be found and remedial measures can be instituted. This additional therapy is sometimes sufficient for the restoration of the proper balance in the detrusor-sphincter mechanism.

Patients who are recovering from a lesion of the cauda equina have been helped by proper instruction concerning urinary habits. If they attempt to void at regular intervals and do not permit the bladder to become overdistended, they often do extremely well. This might be called "urination by the clock." Some patients are assisted by a canvas band that is placed around the waist; this band provides support for the abdominal muscles when the patient tries to urinate and gives him something to push against. Some patients void much better in a sitting position than when they are standing. Some are helped by additional pressure applied to the abdomen with their hands. These are only a few of the methods that may be useful. Sometimes the patient himself will discover a unique method to assist in urination.

When other methods are not successful in restoring vesical function, reexamination of the neck of the bladder should be done with a view to the possibility of reducing its resistance to the forces of the detrusor muscle and the abdominal muscles by resection of a portion of the vesical outlet. Cystoscopy has revealed trabeculation of the vesical wall in many instances of neurogenic vesical dysfunction (fig. 1). Furthermore, if during cystoscopy the vesical neck is observed carefully during overdistention, it will usually be seen that the so-called internal sphincter undergoes spasm, during which it may narrow to a fraction of its original diameter (fig. 2). This is evidence of imbalance of the intrinsic mechanism.

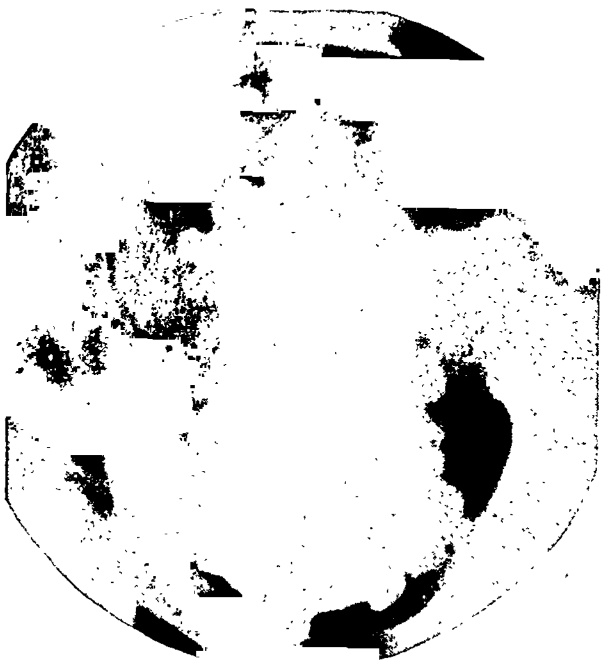

Fig. 1.—Cystogram of a typical cord bladder.

Jacobson sectioned the right pelvic nerve in a dog and produced unilateral hypertrophy (right) of the vesical musculature. The exact cause of this hypertrophy is not known; however, it would appear logical to assume that it is produced by imbalance of the nerve mechanism. When the upper or detrusor portion of the bladder contracts and attempts to expel urine, the sphincteric portion should relax but instead it becomes spastic and resists the outflow of urine. Inevitably this leads to thickening of the detrusor muscle, formation of cellules and diverticula, and finally to back pressure on the ureters and renal pelvis.

Some patients void much better in a sitting position than when they are standing. Some are helped by additional pressure applied to the abdomen with their hands. These are only a few of the methods that may be useful. Sometimes the patient himself will discover a unique method to assist in urination.

When other methods are not successful in restoring vesical function, reexamination of the neck of the bladder should be done with a view to the possibility of reducing its resistance to the forces of the detrusor muscle and the abdominal muscles by resection of a portion of the vesical outlet. Cystoscopy has revealed trabeculation of the vesical wall in many instances of neurogenic vesical dysfunction (fig. 1). Furthermore, if during cystoscopy the vesical neck is observed carefully during overdistention, it will usually be seen that the so-called internal sphincter undergoes spasm, during which it may narrow to a fraction of its original diameter (fig. 2). This is evidence of imbalance of the intrinsic mechanism.

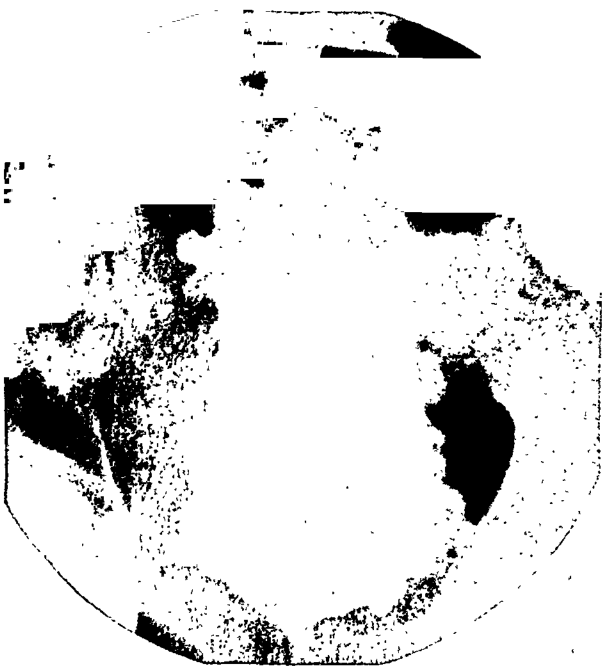

Fig. 1.—Cystogram of a typical cord bladder.

Jacobson sectioned the right pelvic nerve in a dog and produced unilateral hypertrophy (right) of the vesical musculature. The exact cause of this hypertrophy is not known; however, it would appear logical to assume that it is produced by imbalance of the nerve mechanism. When the upper or detrusor portion of the bladder contracts and attempts to expel urine, the sphincteric portion should relax but instead it becomes spastic and resists the outflow of urine. Inevitably this leads to thickening of the detrusor muscle, formation of cellules and diverticula, and finally to back pressure on the ureters and renal pelvis.

Bors, in discussing transurethral resection, stated: "large surveys from Veterans Administration Hospitals demonstrate that the method was used in from 11.4 per cent to 20.4 per cent of cases." Among the 623 patients observed by Bors, 71 underwent transurethral resection; good results were obtained in 95.8%. However, in 22 patients transurethral resection was supplemented by pudendal anesthesia, pudendal neurectomy, or subarachnoid alcohol block. Transurethral resection was employed in 57.8% of the series of 101 cases of cord bladder that have been reported previously by my group.[6] The operation failed in only 1 of these 58 cases and it is my opinion, in retrospect, that, if supplemental pudendal neurectomy had been performed, it would have been helpful in this case.

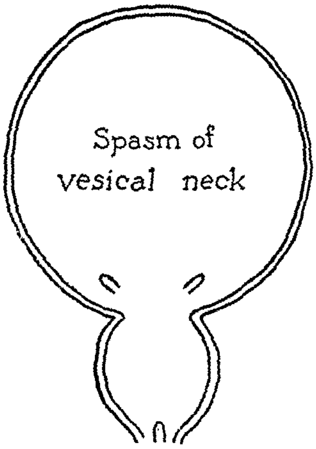

Fig. 2.—Typical spasm of the vesical neck in cord bladder.

Transurethral resection is indicated in the treatment of any patient who has a cord bladder and who has repeated episodes of infection in the urinary tract or who has extreme difficulty in voiding. A substantial amount of residual urine is almost always found. It is for this reason that infection occurs. Formation of calculi in the bladder and eventually in the upper part of the urinary tract will almost certainly result. The following case illustrates the value of transurethral resection of the vesical neck combined with other methods of physical rehabilitation.

REPORT OF CASE

In November, 1945, a 31-year-old white man fell five stories and suffered fracture of the 12th thoracic and first lumbar vertebrae, the pelvis, both ankles, and several ribs. He was paralyzed below the hips and was incontinent of urine and feces. Treatment was carried out in a hospital in Norway until April, 1947, when he was brought on a stretcher to the clinic. Considerable recovery of nerve function had already taken place by this time, but there was still paralysis of the sacral and lumbar nerves below the level of the second lumbar segment.

Roentgenograms revealed extensive osteoporosis of the lumbar portion of the spinal column, the pelvis, and the femurs, in addition to the fractured vertebrae. Bilateral staghorn calculi were present in the kidneys, together with multiple small calculi along the course of each ureter and multiple vesical calculi. Incontinence of the dribbling overflow type was observed; however, the patient was able to force out a few fluidounces of purulent urine by straining with the abdominal muscles.

Excretory urography revealed moderate dilatation of both renal pelves and the calices. Cystoscopic examination at first glance showed the vesical neck to be widely dilated; some relaxation of the external sphincter was observed. The vesical calculi were crushed, and the fragments were removed. Inspection of the vesical neck with a retrograde lens revealed that there was a curtain of hypertrophied tissue projecting down from the anterior half of the neck when the bladder was overdistended. The posterior lip of the vesical neck did not appear to be thickened or elevated, and no bar was present.
